Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

No, sure not, from the description.
Because it takes two USB ports, it obviously contains one
USB WLAN stick and additionally one WLAN booster.
When using one uSB only it will work as standard stick.

I don't know of course, but that is what it looks like.

More accurate would be "Weatherproofed External Wifi USB adaptor". Not
just an antenna.

Might be, but I mentally ID'ed one cable as the conventional WLAN stick and the other to be a control lead. See, I know of no software to pick whether an internal amp should be used or not used. If the amp were out of the circuit EXCEPT when the other USB cable were plugged in, that could serve to let the user go into distance mode. It would take tiny relays or some PIN diodes to impliment such active switching but it's do-able. (Consider that some FM radios have a LOCAL/DX switch for user control.)

Just a guess.

One of my beefs with most preamplifiers is that, once installed, they _must_ be used; take off the DC and they turn into attenuators.

I'll see what facts I can dig up to support my wifi usb conjecture -- or to demonstrate that I'm a moron.

"Sal"

10. Antenna tuner/Smith chart question

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-02 09:39:48 UTC
From: Wayne <mygarbagecan@verizon.net>
Message-ID: <jdru15$r25$1@dont-email.me>
Source record: 3177

Still having fun playing with my 8.5 foot whip on the metal patio roof, with coax feedline to an antenna tuner in the shack. Operating on 15,12, and 10.

The antenna tuner is a typical t network with series capacitors and an inductor to ground. I was unable to get a match on 15 meters with the antenna tuner. So, I thought I would add more coax to the feedline and move around the SWR circle on the Smith chart. Apparently this provides a set of matching parameters that the antenna tuner can now cope with.

I don't have instruments to measure many parameters, but a rough guess is that the 15 meter SWR is at least 20:1.

So the question is: are there parts of the Smith chart that are going to be more difficult to match, and should be avoided?

Most likely that the whole unit takes more current than 1 usb port can
provide, so like some external DVD drives is needs 2 USB ports.

Jeff

Try rearranging your network, try pi series C, pi shunt C, etc.

Also make friends with someone with a vswr analyzer ;-)

EZNEC sez the feedpoint impedance is around 17-j175 ohms with an SWR
of ~40:1 at the antenna feedpoint. Minimum impedance ~1.25 ohms,
depending on feedline length. Not many tuners will match 1.25 ohms
with reasonable efficiency. In this case, a feedline length of an
integer number of wavelengths (N*30') plus 13 feet would probably
allow for a reasonable tuner match for VF=0.66 coax if you can
tolerate the considerable feedline losses.

Have you ever compared the field strengths above and below the steel
cover?

No I haven't. What would be the practical tests? Example, measuring FS at
x feet from the antenna at y height above the cover, vs below the cover at
what point?

Or, I could leave in the additional feedline ;-)
But a good point is that I have an old homebrew 2 element tuner with
alligator clip configuration. Might give that a try just for fun.

I have one of the older MFJ analyzers, but I wouldn't trust the accuracy at
high VSWRs.

Thanks for the comments. When I used EZNEC I didn't know what to use for
ground, so I used Real/Minimec. I'm showing about 18-j142 as the feedpoint
impedance at 21.1 Mhz, which is not totally out of the ballpark with your
number.

At any rate, I have bought enough telescoping tubing sections to build
about a 20 foot vertical. Final height is subject to approval by "the
Admiral". Fabrication of a more substantial base support will be necessary.

In the meantime, this AM I replaced the 8.6 ft whip with about 13 feet of
telescoping tubing, using the same mobile whip mount clamped to conduit.
Resonance is around
18.7 MHz and it loads up nicely on 18 through 10, with 10 meters having the
highest calculated swr of 17.

With the antenna removed, the feedline shows a 1/4 wave null at 4.33MHz.
This gives an estimated 1/2 wave electrical length of 57 feet at 8.66 MHz,
or with 0.66 VF a physical length of 37.6 ft. That seems about right.

I'll get a Smith chart and see where the existing feedline moves the
parameters. Per your comments I'll try to avoid low r values.

Wish the bands would open back up like they were in Oct and Nov.

Yeah, I had that, then dropped it out. Good catch.

BTW, I looked and found no tech data revealing the internals.

I was thinking, it would be a rough indication what proportion of
power is radiated from the feedline.

Good point, and I'm not sure that the feedline is currently in optimal
configuration.

The feedline lies on the metal roof to the edge, where there is a small 8
turn loop. Then it goes another 6-8 feet to the tuner.

That. and it probably has a way to determine if one or both USB
connectors are connected. Then, depending on the USB connection,
it sets its signal level.

The price is not terrible for an antenna and wifi adapter, however a
4.5dbi gain antenna is a little weak. But that depends on your
application, sometimes you don't want a tight beamwidth.> There are
plenty of cheaper high gain antennas that you can buy
and connect a wifi adapter to.

Here's a 14dbi gain antenna for $40

http://www.wifi-link.com/product.php?action=product&class1_id=1&class2_id=4&class3_id=160&
product_id=1142

Here's a wifi adapter that gets great reviews, I use one.
ALFA AWUS036H for $27

http://www.ebay.com/sch/i.html?_from=R40&_trksid=p5197.m570.l1313&_nkw=AWUS036H+&_sacat=Se
e-All-Categories

Just add a cable to connect them.

There 100s of more antennas to choose from.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

25. nylon rope adjustment brackets??

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-07 12:38:39 UTC
From: Jason Washington <none@nowhere.net>
Message-ID: <je9ecg$1au$1@dont-email.me>

With regular guy wires, we have metal turnbuckles to adjust tension in the wire, but what about for nylon? I recently built an antenna that uses nylon rope for antenna support at various spots. I need to adjust the tension in the nylon rope and I'd rather not use metal turnbuckles as there are a lot of spots that need adjustment and I don't want interaction with the antenna. What's the alternative? Thanks

28. Yaesu Question on topic???

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-08 14:15:25 UTC
From: Tuuk <abraaaa@cadabraaaa.ca>
Message-ID: <4yhOq.48280$2e7.6848@newsfe18.iad>
Source record: 3195

Hi

I have the Yaesu FT530 handheld two meter and 70cm with battery.

The unit is very sensitive. For example, when ever I hold the unit near some devices such as my smart meter, all frequencies show receiving massive amounts of fuzz. When I hold near my phone (Northern Telecom phone with many lines and displays) it also shows full strength noise. Holding too close to the TV also, but other areas away from these things nothing.

What is this unit receiving that would cause it to go useless? Is it measuring radiation? IMF? RF? Gama? Alpha? Sigma? Cilium? Iodine? EMF? When I put it near the granit rocks on my sauna heater it shows a small reading of something, I heard there is radiation in rocks.

Any ideas what the interference is that I am picking up?

It is an older unit I know, are the newer ones this sensitive to area noise?

Any ideas what this is receiving from these devices or appliances that is making me curious?

Thanks again hams for any advice,,,

It's RF. Unless all that noise is on the fundamental frequency,
it seems to be rather open to out of band RF. Which is not too
unusual with the wide band receivers those radios have.
I bet you also get loads of intermod when in the middle of
large cities. :/

Hi
Thanks for the responding.

What RF would be causing that near my home's Smart Meter, that new meter they installed on my home. Are they transmitting the information from that meter? Wow, when I go near that the FT530 is useless. Should I tell the electrical supplier to ground that thing or replace it or something? Seems anything that goes near there is interferred with including mobile phone.

Another side question, do you know a online dealer who sells replacement batteries for that? I would like the FNB 27 with NMHD. I did a search and found some that were 40 or 50 dollars plus shipping. If someone knows a trustworthy source that is economical please let me know the link, thanks

IMHO it's a moot point. Buy a battery pack that takes AA batteries. The best ones being the slow self discharge NiMH batteries. Then you can charge it in a charger designed for AA NiMH batteries, or use an external charger that works with the battery but charges based on the proper way of charging NIMH batteries.

Too many chargers of that era charge by dumping power into them until they overheat and then shut off. The result is cooked batteries. NiMH batteries always overheat when charged that way.

New (available at least 15 years ago), stop charging when the voltage out of the cell dips, which indicates full charge. They can be purchased cheaply in many places.

Geoff.

The effects you describe are normal, nothing paranormal involved,
no Aliens, no brain control and no health danger.
Every radio does buzz and crackle
when brought into electromagnetic dirt.

Just about anything that generates an RF signal will also generate noise
around that signal. The noise is supposed to be so weak that it doesn't
travel far to interfere with other devices. Your handheld is most likely
close enough to pick up that noise, and it is "in band" to the receiver.

FWIW I have a cell tower about 100ft away with an 'if' at 144.000Mhz and
can hear what are probably many conversations going on at once. The
cell operators couldn't care less that it makes the bottom of the band
unusable for me !

Radio Frequency, a electro magnetic field from 3khz to 300ghz.

This RF is a specific freq? RF could just be a general statement, meaning anything RF. So if your voice is about 10000 to 20,000 hz to which then dogs pick up just higher,

RF ?? What a broad statement.

So what about the batteries? Anyone got success or bad luck with a online dealer? I see them on ebay for about 40 bucks, shipped, seems about fair for a 12v.

So, if the feed point impedance was 18-j142, and you used 38' of RG58 (for example, I could not find that info), then you would expect to lose 70% of the power out of the ATU as heat. Of course, it is likely that the power out of the ATU is somewhat less than the transmitter output as the ATU load is some 7+j10, relatively low R (but typical ATUs tend to be more efficient on the higher bands).

Did the Smith chart reveal any of that?

Owen

How were you able to obtain an amateur radio license without knowing the
difference between acoustic energy and electromagnetic energy?

>

Anyone who thinks he's picking up radiation from rocks on his HT probably
shouldn't be messing around with batteries, it might be a bit over your
head.

Is it Nylon or Dacron? Anyway, I just tie knots in mine.

As long as you don't put your ham station next to your Smartmeter, you'll
be OK. If you get the battery from a Vertec industrial supplier it's
cheaper than from a ham radio supplier, so I'm told. Please let us know,
thanks.

dBi is a trick. Subtract 2.5 from the gain figure. Also, I think the OP
antenna was an omni, the panel antenna is directional.

There are loss scales at the bottom of the Smith chart that allow
losses to be included. That's why I mentioned "tuner efficiency"
and "considerable feedline losses" in my posting.

Yes, Thanks for the info

Yes, rocks do emit radiation, especially if they come out of the deep
ground.

As a matter of fact, at our international boarders, when there is a truck
load shippment of granite countertops coming through, their x-ray machines
cannot scan those trucks because of that natural radiation coming from those
rocks so contrar to what you may believe, rocks do emit radiation.

The smart meters do emit a massive amout of RF now that I have learned and
it is a big problem in some states like California where groups are now
rising against it. Because of it.

While today we micro manage our health in so many ways, I like to refine
where I can. Yes, I know some old hams who worked next to 2kw linear amps
their whole life, nothing wrong with them, however I am curious to learn.

Hi David

I wasn't really asking about acoustic energy, I was asking about RF energy, frequency, radio frequency. Not sure where you came up with your assumption.

Of course I asked the question, which means I didn't know.

I hope you are not a teacher, I would be an angry taxpayer in your community.

Why not just use the same system used on tents that use rain fly covers?
Not sure how to describe it but you can find them on almost any light weight
tent.
Just use a bigger version.
Most use light aluminum but heavy Plexiglas or Lexan would work just fine.

> Did the Smith chart reveal any of that?

Well, subject to how carefully you plotted the data, you might get a reasonable answer for the line input impedance (as seen by the ATU), but the Smith chart will not directly read the line loss with a mismatched losd.

With a lot of care in plotting, you might scale off the values of G at line input and output, and find the ratio Vload/Vin from the chart to calculate the ratio of Pload/Pin and so find the loss under mismatched load.

The line loss in this case is just over 5dB, more than 10 times the 0.5dB loss you would observe with a matched load.

An exercise for the reader is to use a Smith chart to find the loss under the mismatched load with RG213 where the matched line loss is about 0.31dB.

Owen

PS: if you had in mind using the handy dandy "Additional loss due to VSWR" graph in the ARRL, the line input VSWR is 7.7, load VSWR is 23.7. If you get the same loss figure are mentioned above, it is by accident of the scenario rather than soundness of the method.

Here's a fancy version
http://www.niteize.com/collections/figure-9

I've seen ones that are basically steel wire bent into an appropriate
shape, and, of course, the 3 hole toggle kind: like these
http://www.campmor.com/line-tighteners-2.shtml 8 for $2

The steel wire ones are basically a ring on one end, and a sort of
dual slot thing, hard to describe in words. Functionally identical to
the campmor ones.

And, there's another scheme with two overlapped rings, like you use
for tightening a strap or buckle.

I think that losses were discussed on a previous iteration of the thread, and I have no quarrel with the loss numbers.

Many years ago, I might have been able to somehow deduce cable losses from a Smith chart, but nowadays I just use the published curves.

The current configuration (14.6 ft vertical) is promising for 14-28 MHz operation, as three of the bands have SWRs of less than about 10:1, and the other two are below about 20:1. The antenna is not checked out on all of those bands, but it does an acceptable job on 12 and 10 meters where the SWR is highest. That statement should not be construed as meaning that it is the final configuration.

>are you happy with the way the radio works? Does it work as specified on both UHF and VHF?

As he didn't answer here, I'm guessing it was just a spam post, but I did buy an FD-880 and will give you my impressions of it.

It is a very solidly built radio, compact and with a great feel to it. It has 128 memories, but they are not divided into any banks, nor are any specific to either band. It's a little inconvenient, but I've programmed mine to alternate between VHF and UHF frequencies - ie, all odd number memory channels are VHF, while all the even number ones are programmed with UHF frequencies so I don't have to spin the dial too many times to access one or the other bands in memory if I had kept them all together. There is a programming cable and software available for it.

A number of people I have talked to on it are surprised at the sound quality as well as the signal strength. My FD-880 measures 5 watts on high power into a dummy load. The receive audio is outstanding. Clear and very loud when turned up just half way.
Programming takes a little getting used to, but isn't that the case with any radio? Anyway, once you've gotten used to it, it's a snap.
There are 2 features I don't have much use for, but I'll mention them anyway. That's the FM radio, (the 76 to 108 MHz broadcast variety) and stopwatch functions. The FM radio works, but that's about the best I can say for it. You can program 9 or 10 stations into their own memory locations to be recalled at any time. If you are listening to the radio, and a call comes over the VHF or UHF frequency set, the FM radio function will be interrupted so you can hear the programmed frequency.
The stopwatch - the best thing about the stopwatch is that it can be disabled in the menu! ;-) Using the stopwatch disables the transmit and receive functions.
This radio is well worth every penny paid for it, and I wouldn't hesitate to buy another.

Cons - yes, there are a few, but in my opinion, minor.
The "meter" bar shows full scale on any received signal - or more accurately, it is only an indication that the squelch is open, not of signal strength.
I read, (and have confirmed) that the DTMF tones are coupled to the transmit audio via the mic from the sound from the speaker. This means that if you have headphones on, the DTMF tones can not be transmitted because the mic can not hear them. Same holds true if you simply have the volume turned down all the way. It they don't come out of the speaker, the mic can not pick them up to transmit them.
The only way to charge the batteries is when they are attached to the radio. When you plug in the charger, it powers the radio up, even though the radio is

turned off. It bypasses the on/off switch when charging, but seeing as the power switch is part of the volume control, at least it's turned all the way down when charging. The only sound you can hear is when the squelch, (for which there is no control except in the menu) opens and closes, it makes a click or pop sound from the speaker.
Weird, but I guess that's why it cost me less than $100.00 US even with a spare battery and shipping included.

That's all that comes to mind at the moment. I hope it helps. I really do like this radio. My HTX-204 is a better radio, but I grab the FD-880 when I go anywhere. That should tell you a lot.

news:jeg89n$1q1$1@dont-email.me:

> Many years ago, I might have been able to somehow deduce cable losses
> from a Smith chart, but nowadays I just use the published curves.

An email correspondent suggested the radially scaled "SW LOSS COEFF"
gives a direct reading loss under mismatch from the chart.

There are assumptions that underly that scale, pre-requisites if you
like for it to be accurate. They are explained in Smith's book: "If a
waveguide is one or more wavelengths long, the average increase in
dissipative loss due to standing waves in a region extending plus or
minus one-half wavelength from the point of observation may be expressed
as a coefficient or factor of the one-way transmission loss per unit
length".

So, it does not apply to a feed line of less than a full wave, or any
residual of less than a full a wave after working out the additional
loss in each of the full wave segments of a line. It is tedious and
accurate only for lines of integral full waves length.

The potential error applying it to arbitrary line length ranges from
insignificant to huge.

The graphs in the ARRL suffer the same problem, and IIRC they do not
state the assumptions.

The Smith chart solution I described in my earlier post works for
arbitrary line lengths, and properly reveals the cases where loss under
standing waves is less than matched line loss. TLLC
(http://www.vk1od.net/calc/tl/tllc.php) also calculates the loss
correctly for arbitrary line lengths.

The beverage antenna seems to be an excellent mw receiving antenna.

1) Is there a reasonable minimum length?

2) The beveage is supposed to be grounded through a resistor at the far
end. What type of resistor and how much ohmage?

There are several antenna books which make the same suggestion, so I have no way of citing the original source.

They all sugest you take a mechanical hour timer and connect a terminating potentiomiter to the shaft of the timer, start the timer and record the noise from the antenna. Note where it reaches the minimum.

A more modern possibility is to use two HT's and have one person monitor the noise, while the other adjusts the resistance.

You probably could do it with a laptop, wifi and skype, but that may affect the results.

Geoff.

The answers to all your questions and some you haven't thought of are
answered in ON4UN's book: Low-band DXing. See ARRL for the book. Great
reading any time.

David

Are you a licenced Ham Radio operator? I mean have you written the examinations held by an accredited outfit worthy of providing you with a certificate? I have. Enough said there because your childish mud flinging means nothing.

I asked a question, means I wanted to learn somethings, and this group has a lot of knowledge in it and is a wonderful resource. I guess my next question is how to block out the trolls, the wanna bees.

I reiterate my statement, I hope you are not a teacher, very poor teaching skills. I can almost predict with great certainty that you are not a teacher. None of your advice or comments were constructive, or informatonal or helpful. None.

I wouldn't even want you as an employee, with that negative do nothing, add no value attitude, wow, I wouldn't even want to work beside you.

However, without knowing you I can estimate you have more knowledge about electrons, protons, rayons and electronic circuitry than I do. I will give you that David, however I can bet you dollar to donut that my list of credentials is far longer than yours, so while I may be more versed in a wider range of knowledge, yours is specific to your hobby. Or maybe a profession for you, obviously you are completely knowledgable about electronics. Completely. Not me, I have a base knowledge of electronics, enough to keep me happy and do what I want to do with electronics like building my own antennas and so forth, just the basics. I would need help to repair a rig if it fried. Unless is was an older rig, then I could probably repair, but I am sure you could repair even the latest advancements in our technological world.

I haven't paid anyone to teach me about RF, so no need to "go back and get my money back" so your insults at my teachers holds no water. Not sure why you would even say such a thing.

I mean I asked a question about RF and you answered by saying "Perhaps you should go back to whoever taught you about RF and get your money back then". See, I can parse you also.

That is why I said, "I hope you are not a teacher, I would be a upset taxpayer in that community". Because if you are a teacher and the student asks you a question, lol,,, o my,,,

Are you the ham who complained about me fixing my own furnace not long ago? While I don't have a certificate there either however 10 years ago I installed it myself, now I needing to replace or fix some parts, but you

said "Hire a qualified, certified technician". So I did, paid him to diagnose the problem, he said it was the fan relay board, I bought a new board from a friend, replaced it and exact problem remained. Turned out to be the reset button on the high temperature limit switch control. I didn't know there was a reset button and your qualified certified technician didn't know it also.

Are you the same chap who said to me that rocks don't emit radiaton? Well in fact they do, they do so much to a degree that it is a well known fact, while I am not sure if it is gamma, alpha, etc etc or what, but I know they do. Because you said " Anyone who thinks he's picking up radiation from rocks on his HT
> probably shouldn't be messing around with batteries, it might be a bit
> over your head.""

That is what you said David, and you were wrong, because all rocks coming out of the ground do emit certain forms of radiation, I recommend you google that. There you go David, you are not as smart as you set yourself out to be.

Anyway, great group here, lots of knowledge of wide range of knowledge and I will certainly ask future questions of this group, lots of knowledge here and most appreciate all the help I have received, as I am simply interested in learning, love learning, love learning new things and doing things myself.

In the future David, if you see my post, asking a question that you have a wealth of knowledge, instead of trying to make me look even dumber, or trying to make you look even so much smarter than me, just ignore my post. I suppose the proper thing to do is to add you to some kind of a filter on this newsgroup, I suppose I could filter you out because I don't believe you have added any value to any of my question, only critical of my level of knowledge and critical of my teachers. So David, just ignore post made by me if you don't mind. I have never filtered out people yet on here, I don't filter out those smut slut advertisements, I just ignore them, I suppose I could if I had to filter out both David and the Smut and Slut Advertisments, but would rather you just ignore them. I suppose I could ignore your post also David, your post have never, ever added any value that I have seen, so I suppose I should just ignore them. I wont be trapped into any more of your mud flinging games, I suppose it is just a bait and trap for you David. But good luck with your wealth of knowledge, I hope you use it in a good way.

Thanks again all for your answering my questions, truly appreciate it.

My god, what arrogance!

Perhaps you should go back and re-read your initial post; it was totally incoherent and laughable, and you now have the temerity to criticise people who comment on that.

What are 'rayons' by the way; more modern nylons?

Jeff

Hi Jeff

Thanks for the flowers.

I guess you also are another add on to some kind of a kill file filter list.

I am going to have to learn about how to filter out what you don't want and leave open what I do want.

Why would posters want to come back with negative mud flinging when someone obviously hasn't the knowledge and so asks a question.

Did I say that properly Jeff? Did you understand it? Was it coherent or laughable?

Just because some of you people have more knowledge in something than I, and then when someone asks you a question about that topic, you feel the need to enforce that fact that you do have more knowledge in that topic I asked about. Then you rub it in, and grind the student (or one asking the question). Just because it is so obvious to you, after your years learning the topic in whatever school and you are well versed in the topic, wow, that gives you the right to hammer down on someone who hasn't the level of knowledge in that topic. You think because you are confident in a topic that only an ignorant person would ask about that topic, so you must enforce that fact that the person is ignorant in that topic.

Did I say that properly Jeff? Did you understand it? Was it coherent or laughable? lol,,,

Wow, what happened to the Hams I know? I been around for a while and know many many awsome hams, great people, and a lot of the most intelligent people I know. I guess just like the education system, when you lower the bar, this is what you get. The Jeffs, The Davids, the Einstiens who are smarter than everyone. lol,,,

Did I say that properly Jeff? Did you understand it? Was it coherent or laughable?

Come on Jeff, back to you,

Your first post there was pretty dramatic, pretty theatrical, but had nothing, I repeat, nothing to do with my question. Why respond to my question when your answer had nothing to do with the question?

Did I say that properly Jeff? Did you understand it? Was it coherent or laughable?? lol,,, Come on Jeff,, you are just baiting me now, nobody can be that ignorant. Nobody.

Anyway, I will learn how to use my filter on this News group,,, it seems there are a few trouble makers within the masses. Please from now on, when I ask a question, and I will, about something you are professor of world knowledge on that topic, 1st in your class, top of the crop, world master in the topic, please don't bash me because I am not knowledgable about that topic. THAT IS WHY I ASKED!!!!

I hope you Jeff and David are not teachers, otherwise I would be an upset taxpayer in your community.

Anyway, ya, I will just filter out the riff raff because when I ask a question from this group, off topic or otherwise, I am thankful for all the intellegent responses. Most thankful. I guess you get some bad with the good. But don't criticize me because I don't have the same level of knowledge as yourself on a certain topic, that is why I asked. And please forgive all your students who don't have the same level of knowledge as yourself (if you are a teacher). I hope you are not actually, but some advice from a life time learner, don't bash your students just because they came to you to learn, that is unprofessional.

And Jeff, you asked what a Rayon was, it is an improved version of certain fibers, like a silk, or man made fiber. I am not sure if it is used for nylons. Maybe.

Anyway, thanks for responding, thanks for coming out.

He doesn't have one. He claims to be licensed, but it's obvious he isn't.
Just read what he writes above, and in his other posts. There is no way this
guy is licensed.

Are you kidding me?

Why would I ask about batteries for my FT530 ? Duh!!!!

I know, I know, I do use it for communication with my boat from land, I do enjoy using it for marine band use also.

Why would I ask a question about clamping my satelite dish onto my self supporting tower? I was curioius about gnding there as it isn't actually yet.

Why would I ask a question about my Sauna after I built it? I mean only a Ham would design, build their own sauna.
Why would I ask a question about my furnace? I mean only a Ham would completely install their own high efficient furnace.
Why would I have been a long time lerker in this news group?

Are you sure you are a ham? I mean if you are simply a 2m appliance operator simply always talking about their ailments, well that is my best guess. But you know, I don't actually believe you are a licennsed ham. Maybe a novice, or beginner, or CBer. Ya, I think you are a CBer. Seems your style.

To the chap who said about me "He doesn't have one, he claims to be licensed, but it's obvious he isn't. There is NO WAY this guy is licensed"

To this chap, would you care to put your money where your mouth is?

Be a man, or I bet you are one of those CBers who hangs around on Channel 19 badmouthing the truckers.

So, do you care to or not?

Nuff said., I didn't think you would, but I am willing to put up say,,,, 1g ,,,,

hmmmmm , I didn't think so,,,,,

anyway, you guys are just baiting me, you are poking sticks at me and hiding in the comfort behind your microphone,,, typical CBer tactic. Na,,, not my style.

What did they call you guys on the CB again,,, I forget,,, were you CB Heros?

Jeff and David,, lol,,, Breaker Breaker 19,,, any truckers out there? ,,,, lol,,,,

Ya, I know you are baiting and playing with me now,,, It is ok boys,,, but really, get your licenses,, the ham bands are much more interesting than the

CB bands.

But if that is your level then good for you and be the best you can be.

When I was in the Air Force we had some that didnt look too far away
from a dog bone insulator if you use your imagination a bit. I made
some for tarp tie downs by welding some nuts on the the end of some

steel rods. The threads in the nuts gave it a really good grip.

Hi again,

I am sorry for stirring up a hornets nest here, I didn't expect some of the negative comments, maybe I will try answering my own question through google,

Do rocks give off radiaton,

Certainly they do, to whoever it was who suggested I was ignorant or should not work with batteries because I asked the question, I wanted to know the type of radiation, level of harm, especially on my sauna rocks, well the answer is yes.

http://wiki.answers.com/Q/Do_rocks_give_off_radiation

http://www.epa.gov/radiation/radionuclides/radium.html

http://en.wikipedia.org/wiki/Gamma_ray_logging

http://wiki.answers.com/Q/Do_rocks_give_off_radiation

http://www.furryelephant.com/content/radioactivity/background-radiation/

http://www-formal.stanford.edu/jmc/progress/radiation.html

Second part of my own question was about my new smart meter they put on my home. My FT530 goes off the chart when I am near it, I asked why and if the radiation or RF from there was serious. I will answer my own question through google.

Yes, Smart meters give off a lot of radiation and it is serious.

http://www.electricalpollution.com/smartmeters.html

http://electricsense.com/2225/smart-meter-radiation-3-things-you-must-know/

http://www.youaretheanswer.ca/radiation-sources/smartmeters/

But basically sometimes some of you give a wonderful rant on the topic, I enjoy very much from a Hams point of view. Very logical, very interesting, usually right on and usually intelligent. And usually accurate. So I asked the question

Why some fling the mud? Maybe you just wanna argue or rag chew or whatever, but the Hams I always knew were most eager to help, most eager to share their knowledge on the topic, and I still know a lot who are like this.

I still would like to hear some Ham's opinion on these topics, there is no geological newsgroup that is active, already tried, so those chunks of

beautiful granite I have on my sauna heater came from deep below the earth's surface in Northern Ontario and my 530 does show activitiy when near them, not near as much as the smart meter, I know it is sensitive. And I know it is small amounts of RF, so just curious

Hello, and the chapter "Long Wire and Traveling Wave Antennas" in "The
ARRL Antenna Book" gives theory and practical Beverage antenna designs
for one- and two-wire types. For the case of a one-wire Beverage a
non-inductive terminating resistor in the range of 400-600 ohms is
typical. It should be emphasized, however, that the precise value of
the termination has to be determined by experiment for optimum rejection
of rearward signals. Sincerely, and 73s from N4GGO,

It is about 10' from the feedpoint on my 80m horizontal loop, and about 6 feet from my Yaesu HT in its charger base. The meter uses 900 MHz spread spectrum and I do not expect any ill effects. I already have half a dozen wifi signals here, besides my own, and the steel plate in my head hardly sings at all.

dave r
kd6il

Source record: 3090

Hey, That is great news Dave (if that is your real name, because you like to use two names, hmmm).

Mighty coincidential that you happen to receive it the same day I posted about it. Are you sure you are not trying to make up more stories? Hide some embarrassing comments? Because you were wrong Dave, I must point that out Dave, you were wrong. But a quick post by yourself doesn't change it or hide it, you gave wrong advice. I asked a question, you gave wrong answer and I proved it to you. You can scramble to fabricate anything you like Dave, shows your level of integrity. I think you lost face.

And great that you instantly googled it to find out the details and facts about it, as a few days ago you knew nothing about it. I guess you can thank me for your new desire to learn about your (new) smart meter.

You changed your tune also about that bet I said, I said 1g because you claimed I wasn't licensed. However a list of credentials is also an easy win for me but I think by the amount you have already lied and tricked and your false parses, means your integrity level is very low. Not trusted. Maybe it was me who baited you, anyways, not too bright.

Anyway Dave, you can parse me or cust and paste or change my words around all you like. I believe you showed your true self here today, not too bright.

Anyway, I am still interested to hear from knowledgable hams about these topics, I will google more about them and learn more, that is my goal to learn.

I know there are groups lobbying govts and industry because of these smart meters emmitting high amounts of emmissions and while Dave says it is completely safe, a lot of googling that I read claimed it wasn't that safe. I appreciate your try Dave and your input, but I will stick with the other sources available.

Anyways, at least I caught you there in a couple of lies Dave, it wasn't that difficult, you actually shot yourself in the foot. Are you sure you are a true ham? I think appliance operator.

Anyways, I don't want to drum up another hornets nest here, I caught Dave in his fabrication, he tried a desperate yet feeble attempt to recover from giving wrong and bad information, but lost face in the process. At least I oppologized to the group for starting this, I think Dave owes the group an opology. I wont push it though, I will drop it. I just like pointing out the facts.

If you try to parse my comments again Dave (if that is your real name) or whatever account you use (I see you have at least two) please be accurate this time, last time was feeble attempt to cover up your embarrassing facts about giving me wrong advice. Wrong answers, Oh, then 12 hours later your Smart Meter arrives and you are world expert in it,,, lol,,, oh my,,, oh,, that is funny. Sorry dave, that is too funny.

Anyway,,, sorry again to the group,,, great knowledge here, I didn't mean to make fun or laugh at the group's trouble maker, it was just too easy, plus he started it, he said at first things about me that were unfair and untrue and his answers and advice and criticisms were wrong. I had to point that out beyond a reasonable doubt with facts. He really shot himself in the foot.

Anyways,,, (I know, last one),,,, sorry to the group. Great group, love all the advice and help I get from it. I am not trying for a pissing contest, I just asked for help because I know there is a lot of knowledge in this group and some of the side lines the conversations can go are fabulous, i mean when they stay on the topic and I learn more. I am not in for the mud flinging or allowing the Daves out there to bait or trap me, but he was too easy this time, I hooked, lined and sinkered him. I think he did it to himself.

Anyway 73s

No Dave

Not a good idea to simply tie knots in your guy lines.

Because after a while the wind and rain and wind and rain will slowly cause them to come untied. Very bad idea, very bad advice.

You would be wise to at least tape the heck out of those knots, so to prevent them from coming undone, and your tower or antenna falling over. I mean that is the purpose of the guy lines.

But a simple granny knot wont work Dave. Once again Dave, some bad advice. Have you ever owned a boat? lol,,, I bet you tied it up one day, came out the next and it was gone. lol,,, oh my,, that is too funny.

I recomment starting an immediate course with the Cubs, then work into Boy Scouts, they will teach you Dave how to properly secure something using nylon rope or any kind of rope. Never tie a granny knot Dave, you should never, ever tie a granny knot for your guy wire for your tower. Lol,,, your neighbors are probably sleeping on pins those windy nights. Oh my.

Turnbuckles are cheap and easy way to keep tension equal and tight on towers. Make sure your connections are tight and never use granny knots, use clamps or at least a double Winchester,,, lol,,, oh,,, oh my,,, Dave,,, you got me today Dave... Oh stop it... lol,,,, oh my.... Tie your tower with a granny knot... Oh my... lol,,,, Dave you are the limit.

> antenna was an omni, the panel antenna is directional.

I don't consider dbi a trick, just another standard of measurement.
If you use dbd you are comparing to a dipole which has 2.15 db gain over
an isotropic antenna. (I think you transposed to get your 2.5)

>I think the OP antenna was an omni, the panel antenna is directional.

Yes, however even the omni is directional, but in the vertical direction
vs horizontal. There are higher gain omni antennas available.

http://www.ebay.com/itm/20dBi-High-Gain-2-4GHz-RP-N-Omni-WiFi-Router-Antenna-/250790187736
#vi-content

http://www.google.com/products/catalog?q=high+gain+wifi+omni+antenna&oe=utf-8&rls=org.mozi
lla:en-US:official&client=firefox-a&um=1&ie=UTF-8&tbm=shop&cid=18268083184734573997&sa=X&e
i=uRcLT_KKKsfatwfuq4nLBw&ved=0CIMBEPMCMAI

That's why I added,
"But that depends on your application, sometimes you don't want a tight
beamwidth"
Probably all for naught, the OP seems to have gone on to other things.
Mike

The next link will be to a psych medication

My "tower" is a fiberglass mast. It has 3 guys at about 1/5 the way up,
to keep bending force off the base. The rest is 6 tubes stacked up and a
#12 copper wire coming back down the inside. Very graceful in the wind;
it can bend over 90 degrees and always rights itself, just like a good
sailboat should. Cheers.

Nope, Sorry Dave

I didn't mistaken anything. Just pointing out the facts.

But lets not dwell on this matter. I still think you owe me and the group an opology, but thats up to you.

Anyway, Ya, I learned a lot about these smart meters recently, big issue in many areas and many groups are up in arms about them.

I guess that is advancement in technology as I am sure the water meter will become a smart transmitter, more and more our lives are filled with these EMFs all around us.

There are cautions regarding granite counter tops, very high emitters.

Anyway, don't worry about it Dave, lets let it go. Let it be.

As all EME operators know, ok not most of the new digital only types,
dirt and rocks emit PLENTY of RF. So much that EME array design takes
it into account. On 432 and up it is a major problem.

No, an HT won't notice, but a barely halfway decent noise figure
receiver on 432 will.

I did neglect to mention that Tukster reminds me of 2 someones who've
been missing from here for a while.

Both of whom always managed to prove that they really should stay on
their meds.

Don't leave us Tukster, we've needed some laughs for a while.

Simple solution to the knot problem.

Tie your knot's and then use a zip tie to hold it in place - on the
ropes past the knots.

You can buy inexpensive - small GB zip ties in Lowes - for a couple of
dollars per 100 ties.

Tape will also come loose after prolonged exposure to sun and weather.

Then again, I limit most of my purchases of electrical tape to Scotch 33
brand 3M tape. The cheap stuff never seems to hold up anyways.

I put my Yaesu HT next to a heated rock, and weird sounds started coming out of it, and it started glowing.

What is the ITU designation for a radioactive feng shui emission?

88. Off topic question please?

My toilet today is acting up,,, making a noise when I dip my HT into it.

Dave, any ideas? You seem to be knoweldgable in these things.

Should I have tied the TP paper in Granny knots?

lol,,, oh my,,,,, Oh,,, I am sorry,, I just had to.

That is good idea, something to stop the knot from coming undone.

Dave just ties a granny knot on the bottom of his guy wires. Seems to work for him, 1/5 the way down. I was a little worried there as these simple knots can come undone after a few wind storms.

Lol

That is good David,, you are good at making up stories. But not too good at recovering from an embarrassing situation. You see the facts are clear, I asked some advice, your answers were wrong, then you flung some mud, called me a few names, accused me of not being licensed. But I proved you wrong, (smart meters, granite rocks) so now you obviously have googled these topics and have some ideas about them. But still, you are trying to recover from an embarrassing situation where you were caught in a lie.

Don't worry, yes I believe in Feng Sui, very much so. Your comments about my gf are childish, I wouldn't make comments about your family, are you racist also?

It is called Meinze,,, it means Face in Asia,,, you obviously have lost face within your crowd here and now trying to recover some of that "Face". Very important for Asians, but I didn't think western people give a shit about Face. But I see you are trying to recover from lost Face. I wont rub it in Dave.

No, I didn't put my HT beside the heated Granite rocks on my sauna, that is ridiculous, you simply made a story there, nobody is that stupid. That is attempt to make this situation look a bit funny, take some focus away from the fact that you lost face because you got caught in a lie (Oh, my smart meter arrived this morning),,, remember that David? But lets drop it, I don't want to rub it in any further,, I am sure time will help, it will allow all your peers here to forget your ignorant comments and answers to my questions (ignorants doesn't mean stupid, only means lack of knowledge on the topic). Facts show that you were ignorant on Granite Rocks and Smart Meters, but now you have knowledge of these topics. You can thank me David for helping you to learn about Granite rocks and smart meters.

Anyway, I wont drag you though the mud David, lets let it be. You screwed up Dave, got caught in a lie, gave wrong advice, and I proved it and showed it clearly. You can cut and paste, parse whatever you like, You can twist my words around dave, that is not ethical, but you can do it if it helps you to recover from lost face. You can try anything you like Dave to help you recover and regain some face, up to you. Please be respectful. I am just having fun with you now, I wont fling anymore mud. Lets let it be.

Anyway, have a great day

91. LMR 600 N connectors

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-13 21:52:58 UTC
From: JIMMIE <JIMMIEDEE123@YAHOO.COM>
Message-ID: <be936d18-f620-4bc5-af76-ed10c0883e98@p13g2000yqd.googlegroups.com>

I've recently had some problems with crimp on N connectors on LMR 600 super flex cable. Although the connector seemed to be well waterproofed there was corrosion between the coax shield and the connector at the crimp. This problem was found on three antennas that used this connector and cable. I suspect it was a poor quality connector that caused the problem. Connectors plating was peeling off at the point of connection. If someone could advise me on the best quality N connector for LMR 600 super flex I would very much appreciate the advice.

Hey, Dave

That is called Ghosting or Mirroring,, that is illegal.

For you to put my name and my email address in the sign up information then post something pretending you are me.

Not only is that low, unethical, childish, but it is also illegal. If I were to report you to your news server through the Abuse channels, you would receive a warning first, then criminal charges follow. I will not do that. I just like pointing out facts.

For you to even think of doing something this childish, to fling back at me, is simple concrete proof that I must have embarrassed you among your peers here and for that David I am sorry. I didn't mean to embarrass you. Not this bad. Please do not do anything drastic. I hope there are no tall towers near you.

Anyway, come on David, lets let bygons be bygons,, lets live and let live, lets agree to disagree already. I can see this is really bothering you. I didn't mean to upset you this drastically, all I wanted to do was learn something and this is how you treat someone asking a simple question?

Anyway, what you did was illegal, it is called Mirroring I think. Where you took the time to write down all my information, YOU TOOK THE TIME DAVID, you must have spent more than an hour, then you put all that information (my information) and put it on your computer so your posts would look like it were me. I know hams are sometimes old dinasours, but this is as old a game as the hills on Mount Zion there David. Plus it is illegal, plus it is unethical and shows low class. Very low class David, now I must ask you, are you sure you are a legitimate Ham Amateur Radio Operator? This isn't the style of most of the Hams I know David, no, this is low. I think you are CBer. You should be associating with the truck drivers. David, you kind of shot yourself on this one David.

David, you questioned my being a licensed, legitimate Ham, something I think is highly respected, I look up to Hams, I asked you for help. I figured Hams, (and I still do) but I figured are a cut above the rest. This is why I asked you people off topic questions. David, what you have proven to us is that you are nothing more than a glorified CBer. Now I am willing to bet you (remember you wanted to bet me?) but now I am willing to bet you, that there is a CB hooked up in your shack, fully operational. I will make that bet. Funny, last week you wanted to bet me,,, but then you hid under some covers,, you did't follow through.

O well David, what you did today was illegal and unethical... I am shocked, surprised and saddened. I really don't know what to say, I am at a lost for

words (wouldn't you know it?)....

Anyway David, I will let it be,, who knows what you will do next,,, who knows what you are capable,,, and you asked me to put my call sign on signing off? LOL,, is that your style David? Are you going to come throw a rock through my window at 3 am david? Sorry David,, I didn't know who I was dealing with here,, and I didn't expect you to go this far,,, I wouldnt have pulled on your chain this long had I known it would have bothered you this much. For this David I oppologize,,, I will say sorry because I don't think you have slept well for a couple of days,,, all because I dragged you through the mud you were flinging. I am sorry for that. I know how much it bothers you.

Oh well,, try to keep it clean next time David, lets keep it clean. I wont report you, I wont do anything about it, i will let it be. Sorry I ruffled up your feathers there David,, so get over it already. Stop baiting me, I gots better things to do.

Enjoy the weekend,,,

David,,

I am sorry again, I just feel I must correct you here, maybe it is the teacher in me.

But you did it wrong, there is supposed to be a couple of spaces before the Tuuk. You missed that. (not surprised)

Also, Feng Shui has nothing to do with radiation, more of the winds and water. It is all about improvement, improving your life, improving your health. Both yours and my ancesters were much involved in this way of life and utilized it to maximize their wellness. So your ancesters David were very much believers in this David, don't mock them. You can mock me, but don't mock your ancesters there David. Not classy. Anyway, you can google this and learn about it and comment back in a few hours as an expert (again). Same thing with putting my name on your computer and trying to post looking like me,,, don't forget to put a couple of spaces before the Tuuk,,, if you want to perform another illegal and unethical act again David,,, do it right if you are going to do it.

But thanks for attention David. But give me something useful.

Good luck

Hi David

Again, what you did here was illegal and unethical.

You mirrorred me, or ghosted me. Meaning you put my names in your newsreader account so you would look like me posting. But you should have put a couple of spaces before the Tuuk,,, and it still actually shows your server. So very bad attempt at doing something illegal and unethical david.

Sorry I have gotten you so upset david..

100. transporting 16 foot length 4x4's with stationwagon?

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-15 16:45:24 UTC
From: Harry Brown <harrybrown@harrybrown.net>
Message-ID: <jeuvrd$48k$1@dont-email.me>
Source record: 3117

I'm hoping to use these 16 footers for an antenna mast, but I'm not sure how to transport them. I own a Ford Taurus stationwagon that has a rack on top. Delivery fees are way too high for just a couple of posts. Is it possible to transport two at a time with my stationwagon? How would this be done?

Thanks,
harry

I'm guessing that the roof rack of your Taurus consists of rails which run front to back on each side of the roof. If so, your best bet is to fasten two cross members running from side to side at the front- and rear-most part of the rails. Then you can lash the lumber to the crosswise members.

That all assumes that the lumber is rigid enough so that it doesn't flap around under its own weight and that your Taurus is long enough that the lumber doesn't protrude too far front and rear. You might want to tie the front and rear ends of the lumber to the front and rear bumpers somehow, and might be required to attach warning flags to one or both ends.

Not familiar with the Taurus but my friend had a similar issue. He
bought a strap on luggage rack but when he tried to mount it he
discovered it was supposed to strap on to the rain gutter but his car
light a lot of new ones didnt have them. He was able to fasten the
rack in place using bungee cord that he stretched all the way down to
the bottom of his car.

Also, a 16-ft 4x4 is likely to weigh over 50 pounds, depending on
moisture content.

Do with the 4X4's what Mitt RMoney did with his dog: Tie 'em on the
top of the car.

Lay all three 4X4's on the rack with equal lengths sticking off each
end. Tie each one individually to the roof rack, then, tie the bundle
of three to the rack.

Drive normally, but stay a bit below the speed limit and don't take
corners and curves on two wheels.

Hello!

I'm planning to build a parabolic reflector using aluminium net.

The kind of net i found is just a weave of aluminium threads, no
connnection between the threads. Is this going to reduce the performance
of the reflector?

The net is built of 0.4 mm thread and the hole size is 1.5 * 1.5 mm.
I'm planning to use the reflector on the 23 cm band.

I don't know where you live, but there is always a lumber company some where that will deliver small loads for next to nothing or free.

Or if you knew of someone who was a contractor that had a ladder rack on the truck, that could haul them for you, you would be in luck.
I have not done construction work in about 2 years, but I would guess the weight of each 4 x 4 wet would be around 45 lbs.
Most luggage roof racks will not support 180 lbs of this type of weight.
There is no front or back bumper to tie off of and no way to support the weight - because the body of the car is unibody - hence there is no frame, the roof is a part of the frame and you can cause damage to the glass when you put a lot of weight on the roof if the roof buckles.

4 x 4 treated does not make very good mast material.
Use Aluminum or steel pipe.

If you look in Lowes or most electrical supply stores, you can find 1 1/2 semi rigid conduit for about $15.00 a section. They are threaded on both ends and has one coupler supplied with each joint of pipe.
I live in a high wind zone - winds in excess of 65 miles per a hour during storms and my Solorcon 99 antenna has sat at the top of 3 sections of pipe for 9 months now without any bending and it has no guy wires.
There is only 8 feet supported by brackets - so there is 22' of unsupported antenna mast holding up a big long antenna.
Find someone with a arc welder and have them design and build you some wall brackets, preferably out of used steel, (3/16" x 2.5" x 2.5" would hold up a lot of weight with guy wires) and purchase some muffler clamps and attach the conduit to the brackets and the brackets to the garage or shed or side of house and you will have a cheap mast for less then $150.00 if you do it right.

I don't think it is a good idea and would find another material.

First off, long timbers like that will spin and twist after a few months of drying, they would need strapping or something to prevent them from twisting and spinning on you. You should use aluminum or something better.

Second, by transporting those long pieces you are probably breaking some laws in your state, you may get a nice fine unless they are flagged or use lights or proper transporting procedure.

Also, what if the guy behind you doesn't see the flag or logs on your roof extending back 4 feet or more behind your vehicle, then wamo right through his/her windshield and that could be deadly. Very risky to transport like this, get someone with a pick up truck and tie them to the side, front bumper and back bumper and side mirror. Not a good idea but if you had to as it will scratch the side of the vehicle, we used to deliver pipe this way.

Pressure the lumber yard, ask them to be more resonsible and tell them your issues, you only have a short vehicle and their delivery fees are unreasonable, talk to them, I am sure they would agree that the way you want to deliver them is unsafe and unpractical, I am sure they would help out in some way.

But I wouldn't put them on the top of a little car and attempt a very unsafe deliverly like that. You might be on the front page of your local newspaper.

Your taurus wagon is how long? About 15 ft?

Tie them on the rack, not hanging over the back too far. Tie a rope
from the front of the logs down to the tow lug under the front bumper
to avoid side to side swings and too much up/down bounce.

The more you can center it fore and aft on the rack, the better, but
you don't want to hang too far off the back, or you'll need to flag
it. Check your local vehicle code, in California, more than 4 feet
past the taillamps (not the bumper!) needs a flag (or light at night)

Whether you tie them together or spread them out is sort of up to you,
and the construction of your roof rack. I'd probably put them both on
the passenger side, or which ever side has the tow lug in the front.

Obviously, you don't want to be doing your SCCA solo 1 racing in this
configuration.

The other strategy (I've used it with pipes and masts) that's a bit
more dicey is to sling them along the passenger side of the car, using
webbing around the door posts/windows. Wrap lots of towels or padding
so you don't scuff the paint. Flags almost certainly necessary, etc.

A not very good strategy is to stick them all the way through the car
onto the dashboard and hanging out the back window, but I think that
will wind up with 6 ft or more hanging out, and it's hard to secure
them. if you stop fast, they slide forward a few inches, and you just
bought a new windshield. (been there, done that, with 2x12s in a Honda
Civic hatch back.

And finally, the most bizarre, but sometimes works.. tie it UNDER the
car or truck. There's usually structural members, etc. But make sure
you have enough ground clearance. In California, nothing on the car
or attached to it can hang below the bottom of the wheel rim.

Don't overload the rack. Typical ratings are 50-150 lb.

If it helps, I recall a long-ago rule for perforated and mesh satellite dishes. The hole diameter could be up to one-tenth wavelength and the reflector surface would still appear solid to the EM waves. I had a 3m mesh dish for 4 Ghz c-band TV. It consisted of twelve unconnected panels.

I'd say try it.

From my imagination: If you were to set up a normal VSWR test with your 23 cm gear and move a section of the mesh toward the antenna, you'd know somewhat whether the mesh is a reflector or is RF-transparent. Compare the VSWR change to a corresponding test using solid material. Just a thought from my fertile brain (with no mention of what kind of fertilizer).

I had to move a big (disassembled) HF beam antenna with a mini-van. I
used wooden grape stakes(1 x 2) to make an expanded version of the
existing roof rack, such that the cross-members were about eight feet
front-to-back and provided adequate support for the 30-minute trip.
(The stock cross-members can be separated only about four feet.)

I would say the antenna weighed more than one of your posts, but less
than two. Two trips?

Of course, you right, empirical is certainly a good way to decide if the
net is good enough. The secret fertilizer you use seems to work ;)

Typo should have been brain not brail!!

Approximate diameter? How much gain to you need (or expect)?

>The kind of net i found is just a weave of aluminium threads, no
>connnection between the threads. Is this going to reduce the performance
>of the reflector?

It won't reduce the gain, but you're going to have another form of
entertainment. Because the wires in the mesh are not electrically
connected (welded), you run the risk of creating small diodes at each
crossover as the aluminum oxidizes. Similarly, as the wind blows
through the mesh, the wires will scrape against each other, creating
small sparks. I found this problem the hard way when I built a 1.7GHz
WEFAX dish using aluminum window screen material. I spent a few
months trying to isolate the highly intermittent noise sources. I
eventually smeared spray glue on the window screen mesh, and plastered
it with aluminum foil, which eliminated all the noise sources.

Note the C-Band DBS dishes may have holes in the mesh, but the mesh
itself is solid sheet metal.

>The net is built of 0.4 mm thread and the hole size is 1.5 * 1.5 mm.
>I'm planning to use the reflector on the 23 cm band.

A 1.2GHz dish will probably be big. You're going to have some
structural issues to deal with. If you build a deep dish, getting the
wire mesh to make the required bends is going to be difficult, unless
you build it in wedges. If you build a flat dish, the mesh is easier
to handle, but the support for the feed might be ridiculously long.

I suggest you read the details of dish design, especially the part on
matching the f/D
(focal length / Diameter) of the dish, to the illumination angle of
the feed, which has a big effect on the dish efficiency:
<http://www.w1ghz.org/antbook/contents.htm>

Long ago and far away, I had one of those. It was not made of mesh, it was made of a piece of sheet metal that had been perforated. The holes have to be exact, besides the problems Jeff mentioned, they have to be small enough and properly spaced that the dish still acts as a reflector at the frequencies desired.

That's why Ku band (10gHz) dishes are usually solid. The mesh would have to be very fine and precise.

The holes are not there to make it cheaper to produce the dishes, they are to reduce weight and wind loading. I assume in colder climates they are also there to reduce build up of rain water or snow.

Here in Jerusalem we have snow storms every 4-5 years. The last one was enough that the snow caused our satellite dish to malfunction, which was not welcomed by two kids stuck at home. Due to the rarity of the snowfalls, the hilly terrain and the warm temperatures, schools just close for the day of the storm and then reopen the next day after it has all melted.

I'm interested to do some experiment with the stress dish concept:
<http://www.nitehawk.com/432_MHz_EME/port_dish.pdf>

The antenna is to be used at my country cottage, I don't want to convert it to a modern communication centre ;) In the winter there are storms and it can snow heavily at occasions. The stress dish would be perfect to do some experiment with in the summer period and then put it aside for the winter.

4m in diameter is the plan, I expect a gain just below 30dB, if I'm lucky.

The noise would be a real problem as the ultimate goal is to use the antenna in EME works. Maybe a traditional galvanized chicken net is a better choice? There are nets with 13*13 mm, around 1/17 lambda witch should be OK.

I was walking on the beach when I found an odd lump of something with a few wires dangling out of it and in the way that you do, I bashed it with a rock to see what was inside. ;-)

Eventually I dug this out.
http://www.zen31010.zen.co.uk/images/mystery_object.jpg

It's about 6 x 4 cm and about 5mm thick. It's definitely NOT a mechanical component and I think it's perhaps from the base of a radio aerial, probably off a boat. I think originally there would have been a conductor threaded through the "S".

Can anyone confirm this (just for curiosity's sake)?

Tim

If these work at 2.5 GHz, I think you'll be able to use about anything as long as the parabola is correct. http://www.qsl.net/n9zia/wireless/page04.html

Ummm... 10GHz is X band and DBS Ku band is 13Ghz. There are a few
wire mess and/or perforated sheet metal dishes available for DBS
satellite TV.
<http://i01.i.aliimg.com/photo/v1/475037631/KU_BAND_75CM_SATELLITE_MESH_DISH_ANTENNA.jpg>

>The holes are not there to make it cheaper to produce the dishes, they are

Nope. There are black teflon coated dishes for that. Some have
heater wires imbedded in the fiberglass reflector. Also radomes. The
problem with ice and mesh is that the mesh is generally weaker than a
solid dish. Once encrusted with ice, the mesh might rip, bend, or
tear.

Paint it with glossy black paint. I did that to some white fiberglass
antennas. The ice just slides off the antenna once the sun appears.
It's not a total solution, but it helps.

That works for a few days. The problem with reflectors under tension is that they don't stay in any stable position. The aluminum mesh is the worst because it moves with temperature. If you look carefully at various mesh reflectors available, they're usually galvanized steel. However, at 1.2Ghz, the tolerances are much less than at X band or Ku band, so it will probably work.

>The antenna is to be used at my country cottage, I don't want to convert

The uglier the antenna, the better it works. Nice looking antennas just don't seem to function as well as ugly kludges. Might as well resign yourself to building an eyesore.

>In the winter there are storms

My I suggest an infaltable dish antenna? (I'm not joking).
<http://www.gatr.com>
<http://www.qsl.net/pe1rah/RAHdish.htm>
<http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=1203415>
If you want it out of the way when the neigbhors arrive to protest, and inflatable antenna structure might be the answer.

Another design I tried (and discarded) for the WEFAX antenna might be worth raising from the dead. Instead of a dish, it's a parbolic "strip" reflector. It was in the shape of a parabola in one axis (as enforced by several sheets of plywood cut into a parabola like shape), but was less than 1 meter wide. The idea was to obtain the same surface area as a large antenna, but with a very different aspect ratio. That makes it much easier to build, ship, and assemble. I'll see if I can excavate some photos.

>4m in diameter is the plan, I expect a gain just below 30dB, if I'm lucky.

That's a reasonable size without becoming monsterous. No clue if you'll get 30dB. I could do the calcs, but I'm busy right now.
<http://www.antenna-theory.com/antennas/reflectors/dish3.php>
Use 50% of the overall efficiency.

The stability is one of things I want to study - and you're probably right in that long term stabilty will be a problem. I've done some calculation and used 45% efficiency and the result was around 30 dB.

Yes I've thought about single curved parabolic reflectors as you describe, but it would give polarization in one plane only and the standard is circular polarization for EME at 23cm.

I will certainly consider inflatable antennas, funny idea!

Galvanized Chicken net is easier to obtain, cheaper and as you wrote, it was what people used in earlier designs.

That is a double edge sword.
You can get increased propagation when it hits, or you can get a total blackout - like we have had the last couple of days.
The last time I looked, the solar index was only about 88 - which is not good if you want to work 10 meters.
There has been days where you can't hardly hear anything on the 80 meters during the day here and the 40 meters was just as bad and the 20 meters was almost impossible to hear.
At the same time, when the HF bands drops off, the VHF and UHF Propagation increases. A good time to work SSB 2 meters.....

I don't think it will be too horrible as long as the antenna parts and pieces can be adjusted for optimum performance. At 1.2Ghz, that shouldn't be much of a problem. If you were building at 10GHz, I would be seriously worried.

>Yes I've thought about single curved parabolic reflectors as you
>describe, but it would give polarization in one plane only and the
>standard is circular polarization for EME at 23cm.

Nope. As long as the width of the antenna is 1/2 wave or larger, it will work with CP. I don't think that there's any way such a reflector can convert circular polarization into elliptical (but I'm not sure).

>I will certainly consider inflatable antennas, funny idea!

Not funny. I've tried to build an inflatable tower for Field Day for the last few years. Each year, something goes wrong, usually by running out of time. With the proper materials and design, inflatable antennas are fairly simple to construct out of vinyl and glue.

Incidentally, China has a storage space problem. So, for the annual parades and events, all the decorations and props are inflatable. When not in use, they're fairly small. Something like these arches:
<http://www.china-inflatable.com/products/inflatable_arches_1.htm>
Bosch Aerospace used to build inflatable towers for the military. It's now LTA Projects. The videos are fun to watch:
<http://ltaprojects.com>
Yes, they have a ham version:
<http://ltaprojects.com/ham.html>

>Galvanized Chicken net is easier to obtain, cheaper and as you wrote,
>it was what people used in earlier designs.

WELDED galvanized wire mesh, not ordinary chicken wire. Most chicken wire is not welded.
<http://www.wirefenceonline.com/welded/gaw>

As far as I am concerned, the HF bands have been in the dumper for a month
or more. Although I have heard a little more activity in the past few days.

Haven't heard a signal on 6 meters in a long time.

130. antenna calculator for a loaded Yagi or similar?

Newsgroup: rec.radio.amateur.antenna
Date: 2012-01-20 20:07:37 UTC
From: Harry Brown <harrybrown@harrybrown.net>
Message-ID: <jfchicsdf1@dont-email.me>
Source record: 3147

I'd like to try building a loaded Yagi. I came across plans for a 20 meter mini Yagi while Googling, but I want something for 15 meters. Are there any simple, free calculators available? Also, can anyone tell me a ballpark figure how a 15 meter shortened (by 40%) 3 element Yagi would compare to a full sized one? How about if I added an additional element for 4 loaded elements instead of 3?

Thanks,
harry

MMANA has a 3 element loaded yagi as an example.

Http://hamsoft.ca/pages/mmana-gal.php and it's free

Short Yagi W1FBY & WA1LNQ

It's got a gain of about 4.7dB

I dare say 4NEC2 will model it as well.

Hey,

Come on you guys, you forgot again to put a couple of spaces in the name for Tuuk,,, Not very smart. And it is obvious the message didn't come from my server, I don't try to hide.

YOu realize what you did was illegal and unethical, It is called mirrorring or ghosting. By putting someone elses name in the fields as to look as if it were them posting. Not very bright are ya.
But it is illegal, not to mention unethical. Did I mention that?

Feng shui ,, not shei,,, again, not very bright are ya.

And also, it is not a feng shui detector because they do not look like that. Looks more like the cover of a flux capacitor, It is obvious that you haven't lived with a knowledge improved feng shui life,,, oh so obvious.

And what does Feng Shui have to do with my sauna?

Anyway, thanks for thinking about me, and thanks for trying.

The brass object is a sand casting, are those grooves for water? Glue? Prevent it from warping? and the holes for bolts.
What is the other side looking like?

Good luck and 73s

>Are we talking about the same type of reflector?
>I'm thinking about a Parabolic Trough:
>http://www.solar-facts.com/light-concentration/parabolic-reflector.php

Nope. Different form factor. I'll see if I can dig out some photos
(a major project). Mine was very different. Visualize taking an
ordinary parabolic dish, and slicing off a chord from opposite sides
of the dish. The result is a large parabolic shape in one axis, and a
much smaller parabolic shape in the other axis. Something like these,
but with a much more radical aspect ratio:
<http://cdn3.explainthatstuff.com/solar-cooker-parabolic-reflector.jpg>
<http://www.greenjoyment.com/images/butterfly-community-solar-cooker.jpg>
<http://www.dipol.com.pl/pict/a72122+.jpg>
As I vaguely recall, one reflector axis was about 15ft, while the
other was about 3ft.

Obviously the gain will be reduced if large parts of the reflector
disappeared. However, if the surface area of the dish were maintained
by adding to the longer axis, most of the lost gain can be recovered.
Note that most of the gain provided by the dish comes from reflections
close to the center axis (near the feed). As the sides of the dish
get steeper, as in a deep dish, the increase in gain per dish area
added becomes less. When the sides of the dish are nearly
perpendicular to the main lobe, no gain is produced at all. Therefore,
a flat dish (large f/D) is a more efficient use of reflector area,
than a deep dish (small f/D).

>I thought that this type of reflector just have one polarization plane?

I'm not sure, but I don't think it matters. As long as the continuous
reflective surface is large enough, the reflected signal will not
magically convert from circular to elliptical polarization. It will

change sense (RHCP to LHCP), but not symmetry. The problem is that I'm having some trouble visualizing how it works and need to think about this for a while.

WEFAX on 1691MHz is circularly polarized as are most satellites.

The gods of propagation are fickle. I was just in northern California but wanted to check in with my club's 7183 kHz net in San Diego. I brought a 40m Hustler with some radials. It was all set up and tested around 5:00 PM and I worked two guys 5-7 within twenty miles of home. All good, right?

At 7:30, that band was as dead as I have ever heard it! I had only some foreign broadcasters, including Radio Havana at S9. XMIT VSWR was normal; minimum around 7190 and slowly going up on either side -- same as it was in the afternoon. Just no prop. Hated life. Plus it was damn cold out on that sidewalk. ARRL Antenna Book has all the answers.

Shortening the antenna will reduce the effective radiated power and will reduce the amount of gathering ability of the antenna.
Every time you reduce the size by 25% - you throw away - probably 50% of it's ability.

Antenna's are always a compromise when you get into the lower ranges.
It is easier to BUY a Mosley tribander - about $1000.00, then to try to make your own.

As the elements are shortened or lengthened, all of the variables has to be recalculated because the spacing will also change and the boom length.

Do you think they used Granit rocks on their sauna?

Maybe their HT needs new batteries.

Any suggestions? Is this Feng Shuie?

Yes it's the basic one, the file is in

\MMANA-GAL_Basic\ANT\HF short

and the file is called

"3el short Yagj W1FBY.maa"

Hey, Thanks for the flowers,

But what do you suppose the emmissions are in these people's home?

Do you think they were twinkled by the fairy god mother? Or is this some
natural ground emissions or man made transmission lines under them or are
they dreaming this stuff up?

Obviously very serious health concerns.

Any thoughts?

One note.. When designing a loaded dipole or yagi, you can
consider it pretty much the same as designing a loaded vertical,
except you have two back to back.
The same rules apply as far as current distribution, etc.
The only difference is the vertical is half an antenna
fed against ground, and the yagi is two verticals back to
back, which form a complete antenna independent of ground.

So.. if you look at the various forms of loaded verticals,
you can apply the same designs to loaded yagi's.
For instance, up to a point, the farther up the vertical
the loading coil is, the better the current distribution
will be. The tradeoff point where the coil losses outweigh
the improved current distribution, which can be modeled, but
is probably around 3/4 the length of the radiator in most
cases. Maybe slightly more.. I checked this one time, but
forgot the best exact location that I came up with..
Been a long time since I did that.
If the loading coils are at the feed point, that
would have the least desirable current distribution with
a vertical, and this will apply also to the elements of a
loaded yagi.
The farther up/out the loading coil is from the feedpoint,
the more coil turns you will need to tune.
If the world was perfect, and coils had no loss, all
the way at the end would be the best place. :/
In the real world, you have to use the best compromise.
Which averages about 3/4 the way up/out from the feed
in most cases.

You could use the usual antenna modeling program to
calculate the performance, but you could also use
a vertical design program, such as vertload, and
also determine the best place for the loading coils.
You could then use the modeling program to design the
best spacing for what you want to optimize. IE: most
gain, or best f/b, etc.

Placing the coils at 1/2 out from the feedpoint is
a fairly good location as far as coil loss, vs current
distribution. But if you wanted every last drop of gain,
you could go out a bit farther. I probably wouldn't go
any farther than 3/4 out though. You can also use capacitive
loading hats on the ends of the elements. That will further
improve the current distribution, and also slightly reduce
the number of coil turns you need.

RF does not cause skin issues except at very very high power levels.

I'd love to see video of the glowing bulbs. I simple do not believe it.
Evidence is needed. Virtually all of these things are hysteria or fraud.

Dreaming, hallucinating, causing anguish for fun.

Uhh.. not really. for small scale shortening, the directivity will
remain roughly the same. Losses are fairly small, in general, so you
don't get a big change between loaded and unloaded (unless you pick a
particularly lossy way to load it)

What WILL change is that the dimensional tolerances and bandwidth will
be narrower. That is, you won't get the same gain over as wide a
band.

You will also not get as good F/B or side/back lobe performance in
general.

> Every time you reduce the size by 25% - you throw away - probably 50% of
> it's ability.

I don't think so. Can you demonstrate this with a simple model?

The physical size of a Yagi isn't all that closely related to the
effective aperture, at least for 10-20% sorts of size changes. Sure,
go to half or quarter size and losses will start to increase because
of the increased stored energy.

Yes, but today, you've got a LOT of help from very good and validated
modeling codes. No more are you looking at tedious cut and try.

The real thing that's going to affect performance for a small antenna
is mechanical details.. how are elements attached, what kind of
dimensional tolerances can you hold, how big is the tubing, stuff like
that.

162. Icom AH-4 setup question & Morse code tattoo comment.

I want to run a single wire antenna using my AH-4 with my IC-7000 or 706MKII, but living in a 2nd floor apartment, I don't have access to a good ground without having to run a ground wire longer than the antenna wire is going to be! Does anyone have any suggestions on how I can get on the air with this equipment without frying something? I'd appreciate any information/ideas.

Also, I have never had any tattoos before, and was planning on having my daughter's name, (Beth) tattooed on my forearm in Morse as my first. A few days ago I was being set up for radiation treatments where they give you a CT scan and mark, (tattoo) you with three reference dots to aid the radiation techs when they position you and the equipment as they get ready to zap you with it. Anyway, when they did that, I couldn't help but think of them as 3 "E"s tattooed on my chest. One in front, and one on each side. I just thought that amusing.

Anyone else have, or thinking about getting something tattooed in Morse? I'm looking for design ideas. If you know of any pictures on the web, links would be appreciated.

I've been faced with such antenna challenges myself. What bands do you want to operate? The challenges get bigger with lower frequencies.

I had reasonable luck with a horizontal loop near the ceiling (or in the attic) fed with open wire line. If you are going to use an outside end-fed wire, the MFJ artificial ground might help.

I am thinking a improper ground somewhere causing leaking.
Maybe there is infloor heating with the heat resistive wiring and the wireing doesn't have proper shielding and it is spewing EMF. Some manufacturers produce, and brag their selling rights because theirs is 0 EMF. And they do a pretty good job of shielding it.

And EMF if high enough power as you say, will cause mutations in DNA and cancers and problems. Maybe theirs is high power.

Maybe they have ghosts, they could use my HT 530 to measure, It might even be able to tell the difference between a leaking infloor electric heater improperly installed and a ghost.

2nd floor grounds are always a problem. For a friend, I tried a large
piece of welded chicken wire under the carpet. It failed miserably.
Grounding to the plumbing was even worse, as the downstairs neighbors
computer and TV would go nuts due to the radiated RF. Throwing a
heavy copper wire out the window and pounding in a ground rod worked
well, but the condo committee decided that it broke their rules. At
this time, my friend is using various remote HF stations over the
internet.

Been there, done that for prostate cancer. 5 years, and PSA=0. The
hard part is laying still for 20 minutes, while the machine drills
holes in you with protons. Don't worry about side effects. The real
problems are catching a cold or flu in the waiting room, and finding a
parking place.

>Anyone else have, or thinking about getting something tattooed in Morse? I'm

It's just 3 small dots. Try not to gain or lose weight during the
procedure or it will throw their aim off. However, it's not critical
as they run xrays at various points to recalibrate the targets.

As for Morse tattoos, they try to make the target as small as
possible. Adding more targets is not a great idea as they may
accidentally burn a hole in a sensitive place. However, if you must:

I know one of the Daves around here had DORK !!! tattood on his forehead.

Probably to line up their lazer beams aimed at his brain. Certainly would explain a lot.

Anyway, I always figured tattoos to be tabboo and never felt the desire. While putting your daughter's name in code is cool, you will explain it each time to everyone who ask what all those dots are. Could make them flourescent glow in the dark dots. But have too many friends of mine are getting their tattoos removed now. I suppose back then they were done differently, maybe today more safer. Most commendable putting your daughter's name, but remember it is permanent.

Do you have copper cold water pipes in your appt? Could you ground to that with saddle or clamp? Or your outlets on the walls are gounded (probably to that same pipe, off the main box).

Just start off on low power and use that tuner and watch your meters.

If I am not mistaken, I think that unit has a bunch of fuses easily replaceable, and a nice microphone. Dave had one back in Nam.

I remember from 40 years ago Gomer Pyle had two dots tattooed on his
arm. ..
It was going to be a snake but his girl friend stopped him, so all he
got were the eyes. :-)

I said nothing about high power causing anything. You are imagining things.

On cancer and mutations - B as in B, S as in S. Show proof - as in
double blind studies, not hearsay, which seems to be your normal mode of
operation.

And I would love to know how someone can tell the difference between a
heater and a "ghost" using an HT.

Pray tell, explain this to us.

Really.

This should be quite amusing.

Except ultra high power, but that is heating, not mutations or cancer.

You are a perfect representative of current world citizens. You read
something on the net and believe it because you have no scientific or
logic training at all.

This is one reason, among several, why the world economy and society in
general is on a downturn.

If you are typical, which is unfortunately probable, we are all doomed.

Tom

You said """RF does not cause skin issues except at very very high power levels.""

Then you said

"""I said nothing about high power causing anything. You are imagining things."""

Come on Tom

"""Dreaming, hallucinating, causing anguish for fun, it makes no difference. There are no health concerns."""""

These are what you said. Then you turn around and spin like this?

Sorry Tom, you just lost me there.

But then you also said:

""No offense, but you are not as amusing as you seem to think you are. As in - not at all amusing.

You were more amusing, but not much, when you making absurd claims."""

Come on Tom,
Who is amusing who? I think it is you who is making "absurd claims".

And I have proven it beyond a shadow of a doubt.

And yes, I can prove that EMF causes health problems, easily, you said they don't.

hmmmmmmmmmm

73s

""No offense, but you are not as amusing as you seem to think you are. As in - not at all amusing.

You were more amusing, but not much, when you making absurd claims."""

I have a friend now who is having a big face removed from his arm. It is a big proceedure to have this thing removed and has taken over a year so far and big bubble blisters and long process and probably expensive and avoidable. The eyes were different colors so much more complicated and painful.

But putting your daughter's name there is commendable because that is a life long thing. But morese code, well what if you are not a Ham for life? I know some hams who say they are hams who couldn't spell ham. I know some ham wanna bees, and I know a lot of good hams, real hams. Some go, some come and go, some just hang around like a linguring odour.

What made you think of this? Is this pier thing? All your friends have some tattoos? Your papa? Some like to become 2nd or 3rd generation doers, I understand that, I am like that. But it is your choice,,,

Couldn't you just put her name on your shoulder? Like a sea captain puts an anchor on his arm?

Good luck with your decisions and treatments and what it is to do.

```
Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to

176. AEA ISOPOLE antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2012-02-02 22:24:09 UTC
From: JIMMIE <JIMMIEDEE123@YAHOO.COM>
Message-ID: <ba79c798-6d7e-4b8e-9659-c04527de06ae@w4g2000vbc.googlegroups.com>
Source record: 3043

I have the cones from a 2M AEA ISOPOLE antenna and I am tryig to find information on how to fabricate the upper radiator. One thought was to use a mobile 5/8 antenna that screws onto a UHF connector. slot the end of the mast so it can be clamped to the connector with a hose clamp and then mountthe cones per the AEA assemblyinstructions. My first attempt to do this was a failure but the old antenna I used may have been bad. Before I throw good money after bad I was wonderig if this should have worked.

Jimmie

177. effect of close property fence on dipole arrays and solution?

Newsgroup: rec.radio.amateur.antenna
Date: 2012-02-03 01:14:41 UTC
From: Bill Peters <peterswilliam2591@excite.net>
Message-ID: <jgfce4$rr5$1@dont-email.me>
Source record: 3044

I put up a 20 meter dipole array a while back and I don't seem to be receiving the greatest signals. The height is fairly low, about 20', and one part of the array is fairly close to an aluminum fence I have surrounding the property. I'd say the southern leg of the array is about 25' away from the fence. So I ask the question: what effect can fences have on antennas and what are some possible solutions? I can rule out moving the antenna because I lack the room to move it any further away from the fence.

Thanks,
Bill

Since length formulas treat your installation as being close to ideal,
consider that the antenna, being physically lower than ideal, may be too
long for 20m work. I made that mistake with a 40m dipole some years ago and
had to cut it shorter to reach resonance, due to the effect of the
too-nearby earth. (A tuner makes your radio happy but won't solve inherent
problems.

If the the antenna sees that chunk of metal fence as an upward extension of
ground, that just adds to your problem, although 25' away doesn't sound like
a big deal.

Have you access to an antenna analyzer that will clue you to the resonant
frequency of your dipole?

Know also: being too close to ground will cause the pickup pattern to favor
upward, vice off toward the horizon

-
For clarification, is the "dipole array" more than one dipole?

You could configure a reference antenna by mounting a nominal 16 foot
vertical element on the fence, using the fence as a ground. (If you don't
have spare tubing, a wire taped to a bamboo pole would do) Then you could
get an idea of whether or not the dipole is working OK, or the band being
dead.

This works fairly well in my experience.

I have a Gap vertical with the feed 8 feet above ground and a 40 or so foot dipole at about 27 feet. Both connect to an LDG AT100Pro. The Gap needs virtually no matching and on 20 the dipole doesn't need a large amount. RG213 at about 70 feet on each.

It is interesting to compare the two. It also makes one understand why diversity receive antennas are really nice.

By and large the receive signal strength is close, which makes sense given how the new wonder digital S meters work. Transmitting to ground wave stations is as expected (again obviously roughly) when considering horizontal v vertical.

The holy goal of resonance has little to do with the performance of a plain 0.5 WL dipole. Almost all of the power delivered will be radiated. What is sure to reduce performance of a 20 meter dipole is being only 6 meters above ground. 6 meters is about 0.28 WL and thus most of the radiation is towards the zenith. This will be true even if you prune the length of the antenna to have no reactance (to be resonant) at your operating frequency.

The old tale of resonance equating to enhanced performance is, to say the least, an exaggeration.

We do not know how high the fence is nor what sort of grid it has. Since the antenna can not be moved horizontally, not much point in speculating about the effect of the fence.

What will improve performance is to move the dipole higher.

Since length formulas treat your installation as being close to ideal, consider that the antenna, being physically lower than ideal, may be too long for 20m work. I made that mistake with a 40m dipole some years ago and had to cut it shorter to reach resonance, due to the effect of the too-nearby earth. (A tuner makes your radio happy but won't solve inherent problems.

If the the antenna sees that chunk of metal fence as an upward extension of ground, that just adds to your problem, although 25' away doesn't sound like a big deal.

Have you access to an antenna analyzer that will clue you to the resonant frequency of your dipole?

Know also: being too close to ground will cause the pickup pattern to favor upward, vice off toward the horizon

At 20' AGL I'd be using a full wave horizontal loop for receiving. I
transmit with a vertical and use a loop plus the vertical (via MFJ-1026)
for receive. for receive

AT 20 ft above ground the antenna may be performing more like an NVIS
antenna radiating most of the signal upwards. Unfortunately 20M is not
a great NVIS band.

I can help a little. I had an AEA Isopole for 220 donated to the club or me
to resell it. I tested it first to authenticate its value. The upper
radiator on the 220 model appeared to just be an aluminum shaft.

http://www.isopole.com/imagenes/PDF/144e.pdf maay help.

As I recall, there is straight DC continuity to the upper element from the
center of the coaxial cable. Don't know if there's a coil involved.

While I am not acquainted with the design theory, I suspect that the cones
on the shaft decouple the bottom element at some discrete electrical length.
Others may know.

Good luck.

In theory I would think it should work. But I'm not sure of
the values used for the matching section in the original whip.
It shouldn't really be that critical, but it is a dual 5/8 collinear
rather than a 5/8 ground plane. I don't know if that changes things
matching wise or not. IE: are they matching only the upper element, or
both? I'm not sure.. :/
Remember that the upper cone is part of the lower 5/8 element, and
it's overall length including the mast tip above it should be equal to
the upper 5/8 whip. In the original, both the upper and lower elements
were appx 50 inches each, or appx 100 inches total, which does not
count the lower decoupling cone.

I found one matching schematic at this site..
Seems it's a fairly conventional L/C circuit.
The diagram was in the "Facts About Vertical Antennas" file.

Hi All,
I'm on a boat, about 170ft from the utility post.
Recently our cable company switched to the wonderful world of
Digital TV. I got the new digital converter and had no picture.
I took the box back and got a second box, still no picture. So now I
suspect a weak signal and confirm that it is the cable length. The cable
company came out and gave me a better cable than I had installed. At
this point I have a picture but it is intermittent. The signal at the
utility post has 3 outputs and had a four way splitter, I suggested the
cable guy put in two 2 way splitters and give me the stronger (first) tap.
That got my signal to work almost all the time. I'd like to get the
signal to work 100% of the time.
I don't has access to electricity at the utility post, so an amp is
out. Although I could try an amp at the cable box end. Is that reasonable?
I would run two cables if there was a way to make it increase signal
strength.
Getting anymore from the cable company is not an option.
Any ideas to get a better signal?
Mikek

PS.

When the signal fails it seems channel 41 is ok and above 42 it breaks up.
Curious to know if there is an unusual frequency jump between those two
digital channels.

Despite your long 170ft drop cable, were you getting good analogue
signals before the change to digital? If so, it could be that something
is not right. Normally, even if you have had only fairly mediocre
analogues, the digitals are good.

Otherwise....
It sounds like your signals are just too weak. As things are, and if you
can, the obvious fix would be to overcome the substantial loss of the
170ft drop cable by fitting an amplifier at or near the utility post
(not at your end), and power it with low voltage via the coax from your
end (ie similar to a line-powered masthead antenna amplifier). However,
you would need to consult with the cable company to see if they were OK

with letting you do this. It could be that they might be able advise you on the most suitable amplifier to use. It's not rocket science, but you have to be a little careful not to break any of their rules and generally do anything they don't approve of.

That's about 10dB loss at midband for RG6.

> Recently our cable company switched to the wonderful world of

That was just a 3dB boost.

> That got my signal to work almost all the time. I'd like to get the
> signal to work 100% of the time.
> I don't has access to electricity at the utility post, so an amp is

Really? There are such things a power inserters and compatible drop
amps that allow you to power the amplifier over the cable from the
user end. For RG6 18ga stranded that is about 0.6V loss at 250mA and
therefore doable,

> I would run two cables if there was a way to make it increase signal
> strength.

Forget it.

> Getting anymore from the cable company is not an option.
> Any ideas to get a better signal?
> Mikek
>

Use a 15dB gain drop amp with power inserter, but that's just a guess.
Would help if you actually knew signal levels like what the receiver
requires for optimum reception and what the cable co sources. Putting
the amplifier at source gives you a typical system noise figure of
3dB, but putting it at your end limits your NF to 10dB minimum from
the start.

Adding an amp at the cable box isn't all that likely to work... you
can try it, but don't get your hopes up. Unless the amp has a
significantly lower "noise figure" than the RF front end in the cable
box, all you'll be doing is adding noise... the desired signal will be
stronger, but the noise will be stronger yet.

Something you could do, is add a single-port RF amplifier right at the
utility post splitter, where your tap comes off of the feed. You can
buy amplifiers of this sort which are designed to receive "phantom
power" through the coax cable... you'd install a "power injector" at
your boat, which feeds a DC voltage up the coax to the amplifier.
This is probably your best bet:

- It would amplify the signal before it's attenuated by the 170-foot
cable run.

- It won't require a power supply at the post... just at your
boat, where you already have power.

- It shouldn't interfere with the other taps on the
splitter, even when the amplifier is not receiving power from your boat.

You'd be looking for an "antenna mast" type of preamplifier. The
Channel Master 0068DSB or 7777, Winegard AP-8700 or AP-8275 or
HDP-269, AntennaCraft 10G212, or one of the Blonder Tongue Galaxy III

models might do the job for you. You'll probably want a "75 ohm in,
75 ohm out" model, which would connect directly to the 75-ohm coax.

see URL:
<http://www.dbsinstall.com/broadcast/vhf_uhf_freq_list.asp>
41 is 324 - 330MHz and 42 is 330-336 MHz
cables attenuate more at higher frequency.

By ALL means, if you're going to add an amplifier, add it at the
source location, not at the receiver location
Cheap, but good, ones are available from microcircuits. Can you buy a
line driver from your CATV company?

I suspect the 'better' cable is only marginally better. What is the
EXACT cable you're using? what is its attenuation per foot per MHz?
You can buy extremely low loss coax, but you may have to send in your
first born. Go to a local NRTL [EMC Test Lab] and see if they can
(are willing to) order a length for you.

Find the highest channel you wish to receive and the frequency associated with that. Now you can balance the amplifier gain with the cable loss to determine if it will work. Note you already know that 170 ft of ?? cable gets you up to channel 41, so from that number you can estimate just how much drop your receiver can take before it stops receiving.

Are you sure it's a signal strength problem?
The cable guy should have been able to measure the signal at your cable box.
Are the people using the other taps having problems?
If you're on a boat, you might be at the end of the cable run.
In that case, you might be able to get them to crank up the gain in their
distribution amp.
Power at the pole is not a problem. You can get amps that are powered
through the signal cable to your cable box. Getting them to let you
install it
is another matter.
You can get MUCH better wire, for a price.

Signal strength is not the only problem with digital TV.
Reflections in the system can confuse the decoder. Are there
any unterminated cables on the other taps?

I have OTA antenna digital TV. Plenty of signal, but reflections
cause significant drop outs on some channels. More signal won't fix
that. In fact, I have a variable attenuator to REDUCE signal strength.
I tweak the signal level for fewest dropouts.

Might be electrical noise coupled in thru the ground system.

Bottom line is that you pay the cable company for TV reception.
It's their responsibility to provide you with a watchable signal.
You shouldn't have to tell them what to do. They should just FIX it!!

You are quite correct. However, digital is generally capable of working to lower signal levels than analogue. It's amazing how rubbishy digital signals can be, yet still give perfect pictures - but don't expect miracles!

I see that several others have also suggested a coax-powered amplifier. [If the cable company can't give you more signal level, it's the only solution.] As suggested, they should be able to provide a suitable amplifier and power unit - or at least advise you what to use.

The cable company probably has amplifiers that can be powered over the cable run. If not, those amps can be found on ebay. Be sure to get a bidirectional amplifier because some systems send the control signals back up the cable to the cable company (Comcast in the southeastern US, for example.)

That's helpful. however, I do receive channels up to 484!
Dang, just noticed "Lesbo Euro Trash: Big Boobs" is on 502, but, it's
pay per view. :-)

> 41 is 324 - 330MHz and 42 is 330-336 MHz

I thought there might be a bigger jump between 41 and 42
because when 42 was pixelating 41 was always perfect.

I think I'll try the amp, before spending for better cable.

I think I just found a work around, The station I wanted, 42
is repeated on 428 in HD and it doesn't pixelate when 42 does.
The pixelating problem is rare, only a spall percentage of the time,
but very annoying. Ah, the wonderful world if Digital TV.

Yes, it is the loss in the cable.

> The cable guy should have been able to measure the signal at your cable
> box.

No other problems, I'm just way down the dock from them.

Yes that is possible, There are transients in and out so sometimes the
taps are used and sometimes not. I suppose I could make a bunch of 75
ohm terminations, and put on a new one every time it's needed.
However I never noticed a correlation between boats in and boats out.

Ya, but no. It's in a marina and the marina has a deal with the cable
company.
At this point there is talk about putting up an antenna.
The marina has ten cable boxes for transients that need to be plugged in
and connected (I guess keep them updated). So it has become a hassle for
the marina handle the boxes. I just want to lay low and not rock the boat.

At only 170 feet, that should not be a problem. My cable runs down a
utility post, then over 200 feet to my house. It goes to a 2 way spitter
and then about 30 feet to a cable modem. The other end goes to anotehr two
way splitter, one side to a regular TV and the other to a digital box.

No problem with the TV signal at my house, and the internet is around 7 MB
or however they measuer it. That is by my test on the internet and what
they say I am paying for in the speed./

Sounds like they need to send more signal from the main cable to the taps to
your line.

FWIW, our local cable system just converterd to digital and after
installing the cable boxes I noticed that there were usually about 4-6
drop-outs between 6PM and 11PM. I suspected that the problem was at
their end but they sent out a tech who re-terminated the cables at the
demarcation box outside then changed that splitter from 3 output to 2
output. Inside he trimmed about 2m of excess cable from the wall jack
[inside the wall space] and re-terminated that and installed a new
jumper from there to a splitter [replaced] feeding the two cable
boxes, one feeding the TV the other the VCR. He then measured the
levels and the incoming signal was -10dB [just on nominal] and the
back feed level [at the cable office] was -15dB, again just on
nominal. He said that performance was good down to at least -20dB
incoming. My run is about the same length as yours from the
distribution pedistal and is of lower performance that RG-6.
The number of drop-outs is perhaps slightly less, but a new PVR seems
to handle the drop-outs much better than the cable boxes did so they
are less noticable than before. I have also noted that one particular
commercial has a drop-out in it and it is the same everytime it is
run, again pointing to the problem being at their end.

Ok, 200ft of coax. Presumably RG6a/u.

>Recently our cable company switched to the wonderful world of
>Digital TV.

You have been assimilated. Resistance is futile.

>I got the new digital converter and had no picture.

Something is wrong. The nominal signal from the cable drop is suppose to be 0dBm. If there's a splitter involved, they like to crank it up to about 10dBm. Your 200ft of RG6a/u will drop the signal from between 4dB at the low end, to about 6dB at the high end. Your set top box is suppose to operate with a 10dB margin. If you would kindly disclose the maker and model, it might be possible to find the specs. Typically, you'll have at least 10dB margin. Even with 200ft of coax, you should have 4 to 6dB margin.

Drag your cable box and TV over to the splitter and try it on the incoming drop. If that works, move to the ports on the splitter. Make sure that the unused ports are terminated properly. If that doesn't work, call your unfriendly cable company and ask them why they don't have sufficient level to operate your set top box without the 200ft cable. If it does work, find a 200ft RG6a/u cable that isn't saturated with water. Try to get some compressing fittings instead of the crappy crimp type.

Your unspecified cable set top box may also have some user accessible diagnostics which include per channel signal levels. You may want to check those.

I'm not familiar with Knology, but I suspect they do the same thing as Comcast. With Comcast, the lower 72 channels are still analog in my area. If so, you can probably plug your TV directly into the cable, set the TV for cable frequencies, not broadcast, and see if that still plays.

Hint: Troubleshoot by substitution.

Drivel: I spent about an hour troubleshooting my TV distribution system, only to find a brand new Type F "barrel" connector, with no center connections. That which is most obviously correct, beyond any need of checking, is usually the problem.

I take respectful exception to that last sentence. My digital cable box is about 130 cable-feet from the pole. My signal is tapped enroute for digital telephone, tapped enroute for Internet and then split (by me) so I can feed analog signals via a disttribution amp serving bedrooms, kitchen and shack. I get enough from the pole tap to do the job.

Somebody is treating you badly -- maybe the cable company, maybe the marina. Yes, the approach for you to buy and install an inline, remote-power amp at the pole is entirely valid, technically. However, that's not in keeping with reasonable expectations. You needn't roll over so easily. It's supposed to work.

What -- Are you worried you might offend somebody? That "somebody" seems quite okay with kicking you in the ankle. Or elsewhere.

Some better numbers for RG6a/u:
Freq Atten
MHz -dB
10 0.8
50 1.4
100 2.9
200 4.3
400 6.4
1000 11.0

The CATV band is approximately 50 to 800MHz. With 200ft of cable, you
should see 2.8 to 16dB of loss. While there may be problem at the
high channels, all the lower channels should work.

The 4 way splitter has a loss of about -7dB.

Picking a random set top box:
<http://www.zoran.com/IMG/pdf/Simplify_NextGen_STBs_Solutions.pdf>
See Page 3. Sensitivity is -18dBm for 256QAM and -24dBm 64QAM.

At the low end, you have 0dBm in, 7dB loss in the splitter, 2.8dB loss
in the coax, resulting in -9.8dBm to the box. That's much more than
the -18dBm/-24dBm needed.

However, at the high end, things are not so wonderful. 0dbm in, 7dB
loss in the splitter, and 16dB loss in the coax, which delivers
-23dBm. That's 1dB of margin, which is not very good. Still, it
should work on the lower channels.

Looks like the cable guys screwed up.

a. They should be putting enough signal on that cable to overcome the loss.

b. They should be able to measure the amplitude of pilot signals at your
end of the cable and tell you how much above minimums they are.

If all else fails you may need an amp. What Fred means with drop amp is
usually called a "mast preamplifier", like this:

http://www.amazon.com/Uhf-Vhf-Antenna-Pre-Amp/dp/B0018CDGEQ/ref=sr_1_20?ie=UTF8&qid=1328748729&sr=8-20

I don't know this particular one but essentially it should be
weather-proof. It gets its DC voltage via the coax, from a wall wart

that would plug in at your boat. So no need to run a power supply cable up there.

Don't go for too much gain. This dreaded DTV falls apart rather easily on the slightest distortion or cross-modulation. Not sure if the above amp can handle that. You might need a more expensive one. Michael Terrell might know which ones are good. What matters is dynamic range.

Also, make sure you have a perfect 75ohms match at your end. The cable box from the cable company should provide that. if you have Internet and/or phone through them as well check that connection so it doesn't cause reflections. On a boat at sea stuff can corrode quickly.

Oh, and don't dare to watch that boobs channel while your wife's on the boat :-)

There should be no water in the cable, it's only a couple of months
old and both ends have crimp on connectors and are located in a box or boat.

> Your unspecified cable set top box may also have some user accessible
> diagnostics which include per channel signal levels. You may want to

It does have diagnostics, I'm not sure if it is each channel though.
But I can get some info out of the box. I'll be there Friday and I'll
get that info and the model of the cable set top box.

I'm using Comcast at the boat. We are lucky here (I think) in that
we have a choice of two cable companies.

Any idea where channel 428 would be in that frequency range?
That's a duplicate of 4,2 but in HD, and it works when 42 doesn't.
>
> The 4 way splitter has a loss of about -7dB.

Just a point. I may not have made it clear. I had the tech put in two
2way splitters and connect me to the first one. Hoping to gain 3db.
(or 4) and it did make a difference.

I believe that's entirely up to the cable company, you'd have to ask an
engineer there.

http://en.wikipedia.org/wiki/Digital_cable

Quote "For example, a cable company might call channel 5-1 "channel 732"
and channel 5-2 "channel 733"".

Where does the other leg of that splitter go to? And is that end
properly terminated?

Monitor the signal levels at the set top box and see if it coincides
with something nearby changing, such as the dock lights or operation
of heavy machinery. Maybe shove a DVM (digital voltmeter) into the AC
power and see if it moves around.

> There should be no water in the cable, it's only a couple of months

I don't like crimp type connectors. Push on connectors are MUCH
better. Also, if the coax came from Radio Shack, all bets are off as
to the quality.

>It does have diagnostics, I'm not sure if it is each channel though.
>But I can get some info out of the box. I'll be there Friday and I'll
>get that info and the model of the cable set top box.

Digital set top box diagnostics are different from analog. Instead of
per-channel levels, it might have levels for specific channels.

> I'm using Comcast at the boat. We are lucky here (I think) in that
>we have a choice of two cable companies.

If it's Comcast, you will probably still have the lower 72 channels
doing analog. Remove the set top box and plug in your TV directly.

right good question...OP, when you had the analog signal, was there
significant ghosting?

digital boxes might tolerate a WEAK signal but they are intolerant of
reflections.

I respectfully agree! 8^)

I don't know exactly how it's done now, but when I worked in the Cable industry many moons ago, we had a lot of adjustment we could make. Even more, we had variable by frequency attenuators so we could ensure that a flat signal showed up. There was a lot of signal at the amplifiers, and if we really needed more oomph, we could put in a distribution amp. Another amp was really rare.

Yeah, there is something wrong there. For as much as people hate Comcast, when I had cable internet put in, they replaced all the cable from the pole to the house, and a lot inside the house. I did talk them out of replacing the new cable I had put in, but insisted on putting new connectors on them. The measured all the levels and set them high enough that I'd be able to add more televisions if I liked.

Time to call the cable company and tell them you want your MTV.

Why would there be a reflection in a closed cable run?

Ummm... it's ugly. There are up to 10 standard definition or 2 HD
channels crammed into a 6 MHz wide RF slot. In order to untangle
this, you would need to run a PSIP decoder and extract the CVCT
record:
<http://en.wikipedia.org/wiki/PSIP>
to figure out where digital CH 428 fits. It could literally be
anywhere. However, if you happen to have an tuneable notch filter
(which I happen to have), you can stuff it in series with the cable,
and spin the dial until the signal disappears. Then, just read the
dial. (Comcast seems to be putting well paying and popular channels
on the lower frequencies, and obscure junk on the higher frequencies.
I'm not sure if this is intentional, accidental, or my imagination).

Yeah, I saw that. I guess I wasn't too clear. The input signal can
vary over a 10-16dB range, and it still should work. The 3dB
difference between a two port and a 4 port splitter isn't going to
make much difference, exept at the higher channels.

I know about "cable trash" cable installers that used to go around to
different cities, working for different cable companies. I know what
corners they cut, and what responsibilities they shirk off. I know the
difference between them and me. It is way below my pay grade and way
above YOURS. Compared to you, I am the FADM, and you don't even rate 4-F.
Take your stupidity back to your left hand, putz!

I post-wired thousands of ports, and that was over 30 years ago, you
fucking retarded twit. I have done 350' runs through the woods when they
were unable to get the hard line trucks into the area. That's what
happens when the Bengals GM has his house all the way back in the corner
of an Indian Hills cul de sac. Mr Brown was a big dude too. There were
deep wear tracks in his carpet where the big fucker roamed. Outside the
tracks, it looked new.

Did lots of pre-wire too. Worked for General Instrument for the first
year I was out here in Ca as well. That was almost twenty years ago,
asswipe. I was performing instruction for them by the time I left.
The gear FEEDS the cable companies, AND the broadcasters.

You lose. As usual... again.

Said the *TOTAL* fucking retard who doesn't know me, or a goddamned
thing about me.

I did more last week to make the world a batter place than a putz like
you ever has or ever will in your entire, pathetic life.

And it was ALL absolutely telecommunications related.

Yeah, yer battin' 1000 there bub. NOT!

I'd bet cash at Vegas that you've never even seen what a 10Gb/s optical
port looks like, much less anything about its operation.

The only thing about "10" you have familiarity with is YOUR IQ.

You must be some cable trash asswipe residential hole popper
"installer" wanna be fucktard.

Yeah, you got the fucktard part right. Fits you to a "T".

Stick that up you TAR, K0 boy! You FUCKING RETARD! FOAD!

No way to know from here, but they may not be able to add another amp.

While I was looking for something else, I lurched into this page:

<http://www.cisco.com/en/US/products/hw/cable/ps2217/products_white_paper0900aecd800fc94c.shtml>

While its intended audience is Internet modem designers, the noise discussions are informative with regard to other signals, too.

My point: When you try stringing too many amps in line, the signal-to-noise ratio (SNR) eventually becomes unacceptable. (Remember the acceptable SNRs cited for 256 QAM and 64 QAM.)

Sorry. I should have said carrier to noise ratio (CNR), not SNR. SNR
applies to post-detection signals. i joined the digital world late in life.

Well, you could add an amplifier at the splitter where (nominally)
there is no power.
Use the coax center conductor for power; inline capacitors allow
signal to pass and feeding center via small choke allows DC but no signal.
Once upon a time there were little adapters that did this AC/DC thing...

Careful! Don't get your dBm mixed up with your dBmV. There's around 48dB
difference! 0dBm is a massive 48dBmV. That would certainly make most
set-top boxes wake up and pay attention!

They go to two other outlets, that are used for transient boaters.
sometimes they are used and sometimes they sit unterminated.
I have not seen my problem better or worse when boats are in or out.
But I have several 75 ohm F connector terminations. It's worth a try.

I'm sorry I got that wrong, they are F compression connectors.
Coax was from the cable company.

My drivel:

At my home, knology recently upgraded there system for faster internet.
A cableman said he heard me radiating a block away. he came in and
changed 7 crimp type connectors in my attic a couple of cable runs.
Speedtest.com went from 6 Mbps to over 11 Mbps with just those changes.

Just an addition to the termination debate, the marina has about 150
taps, I'd be surprised if 30 of them are connected to a tv and the rest
are unterminated. The line generally goes to the utility pedestal into
a 2 way splitter and then about 1 ft of cable connects it to the 2 taps
for the boat owners.

Yup, try it. Transient boaters will most likely not carry the required
set top box around but use the lower analog channels or nowadays maybe
UHF digital. Sort of "basic cable". Then the TV is connected directly
and those rarely have a true 75ohms input.

Yep, that's the way it works. Compression type F connectors work
well. Crimp type are junk. The catch is that there are probably 100
different types of connectors, each with their own compression tools,
intended to fit about 8 different types of 75 ohm coax (RG6a/u,
RG59/u, single shielded, double shielded, quad shielded, direct
burial, etc). Mixing connector types and cables doesn't work. I got
fed up and "obtained" a 1000ft roll of double shielded RG6a/u, a big
of matching F, BNC, and phono connectors, a compression tool, a
stripping tool, and replaced all the junk cables in the house.

I'm sure it's true for Comcast in Santa Cruz, CA. No clue on other
areas. The grand plan is to move all the analog channels to digital
area by area:
<http://www2.insidenova.com/news/2011/jun/22/comcast-removes-scores-channels-analog-cable-
ar-1126652/>
<http://www2.newsadvance.com/business/2011/nov/09/comcast-switching-analog-digital-ar-1448
489/>
Unfortunately, your area may be one of those that have moved to all
digital. Hard to tell from here.

> Mikek

Can you determine if the marina is using a distribution amplifier
driving a big splitter, or is using a single cable trunk snaked
through the marina, with taps (directional couplers) at various
points? If taps, it's easy to install too many taps, or miscalculate
the tap type, resulting in level variations along the trunk.

Not really. If there are long unterminated 75 ohm cables after the
splitter, they are a crude termination. The splitter's backmatch
eliminates ghosting from reflections from the unterminated end.

Those are 'Equalizers' and used to cancel the cable losses. There is
some adjustment in the trunk amplifiers, but some brands just used a
plug in equalizer marked with the rolloff in dB while others had both.
The coarse plugin, and a variable equalizer to level the trunkline for
'Proof of Performance' tests.

In your opinion. If they are delivering the level called for in
their franchise, they didn't screw up. It has always been up to the
customer to pay for or provide extra equipment for non standard
installs.

A power inserter is used to put 9-28 volts DC on the coax, depending
on the amplifer you use.

Google your cable box model. You should able to find ifo on how to
pull up a menu that shows signal strengh. -60dbm is about where my
sigal starts droping out

Jimmie

==========

Yes, but be mindful of the difference between dBm and dBmV. The cable
industry often deals in levels on the dBmV scale.

There are places like this ...

http://www.maxim-ic.com/app-notes/index.mvp/id/808

where you can see some conversion equations. Jimmie's -60dBm equals -11.25 dBmV. Same power level -- different scale.

I have long known level requirements for the TV tuner's cousin, the cable modem. The common DOCSIS 2 cable modems are usually spec'ed for -15dBmV to +15dBmV and the smart operators try to keep inside +/- 12. Thus, you can see that Jimmie's -11.25dBmV is near the low limit and that dropouts become more likely in that neighborhood.

I little bit of google snooping revealed that DTV cable boxes would like 0dBmV and will usually be okay with -10dBmV to +10dBmV. Almost the same.

i hope this helps.

If their company cable box doesn't deliver a useful and reliable signal
I call that screwed up. One pays for a service and expects to either get
it delivered as promised or money back.

Mike's install does not sound non-standard. 170ft cable drop towards
premises which is fairly normal, plus the cable company's set-top box.

Interesting how little you bother to learn about the people you swear
at. At least I can put a sentence together.

And I was leading 10M$ engineering projects while you were installing cable.

There is nothing you can spout that would denigrate me.

Grow up. That is an excessive length drop. A standard drop is under
100 feet. You think you know everything, and that the world has to live
by your rules. You don't, and it doesn't. I'll bet you've never even
seen a CATV franchise, or the dozen of pages of specifications agreed to
by both the CATV company and the local government. The CATV company
isn't a Santa Clause machine, and local governments know why there are
limits to the service provided. If there were't, no one could afford to
build or operate a CATV system. You've never designed a headend, or a

physical plant If they build to supply higher port levels, it has to start at the headend, and requires closer spaced trunk amplifers. The system noise goes up from all of the cascaded amplifers, and the equipment runs hotter, withj a very reduced service life. When you can design an RF distribution system of more than 500 MHz bandwidth and has over 10,000 output ports, with the gain stabilized to a couple dBmv 20 miles from the headend and over a range from sub zero F to + 100 F then you can tell me I'm wrong.

One headend I designed and built was only off by .1 dBmv at the test port on the first trunk amp which was a half mile from the head end. If you can do better than that, I'll listen to you and your opinions

Cool! You seem to know what you are up to.

Can you put rough numbers around what you mentioned? Like what are
providers legally required to deliver at the far end of the drop?

Thanks.

We were required to deliver 0 dBmv at the end of 100 feet of RG-59 or
RG-6 for two sets per the franchise. The system was designed at +10
dBmv at the tap to allow for three or four TVs at the 100 foot range.
That was on a 36 channel system with RCA modulators & HST. It was done
for two reasons. To have a little extra signal available when the
system was built, and for conversion for a 300 MHz plant to a 450 MHz
plant without respacing the trunk amplifiers.

I build a headend & interface to tie two incompatible community loops
together. Ours was a sub split loop, and the other CATV company used
mid split. We used 2 & 12 for pilots, so we fed them Channel 2 into

their return, and down converted their feed to T-9 for our return. That headend had two RCA HSP and a combiner. The interface was another HSP in a large stainless steel NEMA box mounted to a power pole at the boundary of the two systems. A pair of two way splitters were used to route the signals between the systems, as well as into and out of the HSP. The other company wanted us to install a modulator and a demodulator at the boundary to give us audio & video, and another pair from our side so the interface would be baseband. Their design was over $15,000 in hardware alone. My design was under $3000 for all the hardware & labor to install. I had system designers from both sides telling me it wouldn't work, but it did the job with no problems. :)

Very nice. We were much more constrained on the install I mentioned up
the thread a ways. The fiber was fed at E1 speed, which probably didn't
work it very hard.

We had an issue at one point.

This was a distributed proc/data system, one of the first. Each cabinet was a standalone PBX. And you could make 126 of them look like one. And each could survive on its own.

First fiber campus we'd done. Staggered cut to the new infrastructure. Fun stuff.

At one point we had to do the cutover to the other large pice of the system. Each end connected the fiber. 0 signal.

TDR from A end showed 700 meters from A end, 800 meters from end B. Length from A to B is 1500 meters.

The work that occurred because of that was not fun. Had to go get the guy doing fusion splicing.

Joy. Midnight trip to Pittsburgh with the salesman.

Actually it was fun. Not much traffic at night.

Landing pattern at 160mph in between DC9s into Pittsburgh at about midnight. And they didn't like 160 at all. This was scary.

Quickest turnoff onto a taxiway I've ever experienced. Of course the taxiway may not have been one. We didn't care.

Yes, and the fiber was obsolete within a few years after installation,
and is not compatible with the standardized cabling and I/O methodology
in use today. Even modern copper Ethernet is faster than that 20 year
old 100Mb/s obsolete fiber and that number was before the overhead.

Whoopie doo, the ditz knows how to polish a face. Not even required
any more.

Wikipedia is also handy for things you know nothing about!

What's Ku got to do with anything. I was designing and using Ku TWTAs
over twenty years ago. I was system engineering director for several
military satellites systems, including those for the UK and NATO. These
did not use Ku because of the problem with rain attenuation.

P.S. How about a reply using one of the many Linux systems you mention?

Sal, A relative number by any other name would smell as sweet. The
reccomendations for my box is about the same but it works well below
that at least according to what I measure withe the cable box. BTW it
just says 'db'. dBm was an assumption on my part..

Jeff, I installed TVRO systems for several years and used a lot of F
connectors. Suprisingly the ones I found that worked best were the
ultra cheap ones that only took a pair of pliers to fasten These were
the ones with the separate crimp rings. Used with some good quality
heat shrink tubing this eliminated most of the problems you mention. I
dont know why these connectors went away, my only guess is that
someone wasn't making enough money on them.

Yech...

Please try this test. Insert such a crimp type F connector and cable
into some useless piece of equipment with a type F jack. Pull on the
cable hard. In my experience, it doesn't take much to make the cable
and connector part ways. Repeat with a screw on connector. Now,
repeat the experiment using a properly assembled compression type F
connector and cable. It takes considerably more brute force to break
the connection. I think the official minimum pull test is 55 lbs, but
I'm too lazy to Google for it now.

Hiding the workmanship under shrink tube is not very functional. It
will have little effect on the pull test.

Most of the cable leakage problems I've seen (and found) were due to
crimp type F connectors coming apart or badly crimped. That includes
both the hex shaped crimp, and ones held together with a crimped ring.

Bad:
<http://www.fconnector.org/wp-content/uploads/2011/12/F-Connector2.jpg>

Worse:
<http://www.showmecables.com/images/catalog/product/F-connector-RG59.jpg.ashx?format=jpg>

Good:
<http://images.lowes.com/product/converted/783250/783250926510lg.jpg>

I tend to judge people by their willingness and abilities to learn new
things. You fail.

You may know something about CATV and fiber, but it doesn't show.
Instead of taking the time to educate those whom you suspect of being
in error, you waste our time with insults and unsubstantiated
opinions. Your command of profanity is truly impressive, but
misplaced. If someone presented you with your comments, what you
would think of the author?

I can't imagine what personal tragedy has occurred in your life, that
you find it necessary to demonstrate your competence at the expense of
others. If you're truly competent, such a crutch is not necessary. If
you clean up your act, there may be hope for you remaining.

See above. Obviously others can. And yes, I have designed RF broadband power amps. Lots of them. Not just lashing up boxes but the actual transistor level circuitry including layout guidance for the nasty stuff.

Fact is, if a cable company isn't competent to do a 170ft drop they should decline the job. Otherwise it is a screw-up, plain and simple. In our area they'd lose their shirts to the satellite guys because there are many houses like ours where there is no reasonable way to get from the street to the house with a 100ft limit. We have around 200ft that's still there from the early 90's and the previous owner said cable TV worked just fine for them. We are not subscribed because TV ain't that important to us.

The Box is a CISCO RNG100
Only data I know how to get is;
Tuner 537.00 Mhz 2dbmv
TDC 75.25 Mhz 5dbmv
RDC 20.00 Mhz 30.0dbmv Yes 30.0

On the road, will check in this evening.
Mikek

He mentioned running 400 megabuck projects. With his attitude he
wouldn't last 10 seconds in the interview for a position like that. And
if he by chance made it through he'd be gone the first day because of
performance and trouble getting along with anyone.

He does sound like someone who does do janitorial work, now that you
mention it, and is trying to compensate for his lack of success and low

IQ with insults.

Usenet. You gotta love the kooks.

Still easier than having to use blasting caps to find the ends of a broken conduit under the finished concrete floor in a new RADAR site. An old fish tape & blasting cap pushed as far as it would go and BOOM!!!. Then repeat for the other end. Then they used a jackhammer to break out the concrete between the huge floor divots to install new conduit. The electrical contractor had failed to tie the conduit to the rebar & wire mesh before the pour. :)

Or driving ground rods through permafrost in Alaska. We drove 60' of rod and used three tanks of Acetylene to heat the rod to get it through the ice layer outside a military radio & TV station at Ft. Greely.

Yawn. You constantly harp about having to meet specs in medical, but
whine like a drunken jackass when other businesses have to meet their
specs. yes, they could design the sytems to 300 feet or more, but the
cost to every customer on the system would go up. Would you like to pay
an extra 20% to 30% just so a very few locations can get better
service? Oh, that's right. You're too cheap to even have cable TV.

You've got me beat.

I am glad I didn't have to use blasting caps as TDR. But it does sound
kind of fun if you didn't have delivery pressure on top of it.

Sounds like good work. But not up the Giant Rat's standards, I'm sure.

Interesting that he portrays himself as young and uses that reference.
Very curious. Maybe he's old and a failure and not young and a failure
as he claims.

Those were the lowest grade, next to screw on fittings. They had the highest leakage, and shortest service life of all the connectors I ever tested. Did I mention that we bought 50,000 feet of RG-59 & RG-6 per month for cable installs? We were using the Raychem for new work & repairs in the mid '80s. They were the best we could find, both for drop, trunk & feeders. They didn't need a boot, and you would break the cable before a connector would pull off, if installed properly. We had to keep a close eye on radiation to prevent one of the midband channels from interfering with airplanes. 95% of the problems were those half assed separate ring, three cent connectors.

He was a cable grunt when Time Warner built Cube in Cincinnati, so I'd
say that he's at least 50 and still a very angry failure.

That RADAR site was at Ft. Rucker, and the problem was in the area
reserved for the new IFF hardware in the mid '70s. Weathervision was
assigned to the space while I was there, but were were in the process of
moving to another building when I was told I had orders for Vietnam. I
ended up in Alaska instead. Two weeks later that AFRTS station in
Vietnam was overrun and the engineers killed. They shipped parts of the
transmitter that survived the gunfire to the station in Alaska. :(

It's the same as the Cisco Explorer 1540C with some features removed
by Comcast.
<http://www.cincinnatibell.com/shared_content/pdf/tv/exp1540_uguide.pdf>

How to get into the diagnostics:
Press and hold SELECT on front of unit until the MAIL light
starts to flash, then press INFO.
Or
Press and hold PAUSE on remote until MAIL light starts to
flash (around 10-15 seconds), then press PAGE-UP (-).
On some remotes, PAGE (+) might need to be used instead.

I'll guess(tm) that TDC is downstream power, and RDC is upstream
power. (20MHz is in the frequency range used by upstream path).
30dBmV is acceptable as the upper limit is about 55dBmv. Remember,
this is dB's above 1mv into 75 ohms, not dB's above 1mw into 50 ohms.
dBm = dBmV - 48dB
So, your 30dBmv is really -18dBm

The downstream values are also in the ballpark. See:
<http://www.dslreports.com/faq/16085>
The numbers are for cable modems, but the levels should be similar for
DTV. The typical delivered values should be:
-10 dBmV to +10 dBmV "Recommended".
-11 dBmV to -14 dBmv / +11 dBmV to +14 dBmV "Acceptable".
-15 dBmV & +15 dBmV "Maximum".
5dBmV is fairly is good enough and should result in a usable picture.

See if you can excavate the SNR numbers. Maybe there's RF garbage on
the systems (oscillating distribution amp, ingress, whatever, etc).

Sorry to hear that. Had friends that survived intact but were still
damaged goods from that war.

Unfortunately the traffic has nothing to do with antennas.

Things dried up here around 6 months ago. I suspect the people with brains and stories, and some of us remember who they are, are no longer with us or finally bailed due to the noise.

Now all there seems to be is some less verbose hangers on plus script kiddie morons and worse.

If you are so talented that your employers don't care what you say then
tell us who you work for.

You are so much more talented than all of us here and you are so
valuable to your current employer that there should be no problem
admitting who you are and who you work for.

They probably don't care a bit that you swear (very poorly) at everyone
that responds to you.

So fess up mister big cojones, who do you work for?

My bet is no one that counts.

And you have no cojones. None at all.

Respectfully, Michael even though we wouldn't *want* to make a 170 foot drop. it isn't unheard of. And the amplifiers are very capable of handling it. Ind it is very location specific. Getting a decent signal at a marginal location doesn't have any effect on the rest of the system. There are attenuators and there are equalized attenuators that will give a flat signal at the end of a 170 foot drop.

RG6 cable has a loss of around 5 db per 100 feet at 500 MHz. Let's give you 10 db at 170 feet, worst case. When I worked in the industry, I plugged (or designed in) in a number of equalized attenuators. It only affected a single drop, or some times a few. You could have a specific amp running about +10db, and with the equalized attenuator, hit the house around 0, flat.

While some might think that it is bad design, ask the system owners whether they would want to put in another pole, perhaps with a distribution amp, or simply use a 20 dollar attenuator.

The world is not perfect, and my job in the catv world included just about every part, from strand mapping to system layout to in the field work. We needed a balance between perfect and affordable. But the only time there might be an issue was if the system was over-amped, then there could be problems with proof of performance certification. We never had an issue with that.

Bottom line is, a 170 foot drop is perfectly capable of having a nice flat swept signal - and it should, unless the system design itself was bad. Done properly, any issues will be mechanical rather than electrical. But nowadays they have messengered cable, so it's even less likely.

>You did not put forth any effort, you lying piece of shit.

Correct. I supplied the minimum necessary for you to notice that
there is a problem. Think of it as a mirror in which you see the
results of whatever it is you're trying to accomplish. You are trying
to accomplish something, or you would not expend so much time an
effort on something so trivial as insulting everyone within range.
From your response, it wasn't very difficult to determine that you're
not responsive to any feedback, criticism, or suggestions. I know
when to give up, which is precisely what I've done.

Incidentally, the mirror isn't such a bad idea. Look in the mirror
and ask yourself if what you see is what you had once intended to
become.

>You had no
>intention of putting forth any effort either, you lying piece of shit.

Not true. Had you responded with even the slightest interest, I would
have burned considerable time and effort explaining my observations,
offering recommendations, and generally trying to be helpful. (Punch
my name into Google Groups search and see for yourself.) You can
start the cleanup exercise by losing the profanity. If you claim to
be a knowledgeable professional, the first step is to act like one.

>You are just like all the "intelligent" cops out there.
(...)

You probably have no idea how much you reveal about yourself with such
comments. Your search for self-esteem is the surest sign of its lack.

I never said it wasn't.

I will say that you match its sad quality, however. You ain't all that, tom. You jumping into your assessment bullshit proves that.

You do not know me, and you do not know ANYTHING about me, so stop making presumptuous remarks, you fucking bastard! You wouldn't have a nose or a jaw left in person!

These fuckers I have been calling retarded in here wouldn't either, if on the first day I ever called them a retard, the response was in the form of a stroke across the face for what they said that caused me to call them a retard to begin with. But the details go over your head pretty quickly, eh?

You jumping on their bandwagon is a serious character flaw, and I spot it immediately, idiot. And that is why you get the moniker even before you think you did anything wrong. Just getting in their fucked in the head gossip sessions makes you a convict, asswipe.

And you are such a dumbfuck that you say I need to seek help? HA!

No, idiot. I moved the line, and simply failed to delete the original.

But I wouldn't expect an immature little bitch like you to have any
vision of reality, even when it is right there in your face.

Just remember,dipshit. *You* are slow scan. *I* am at a rate in which
the very first packet carries more data than the entire set that
encompasses what you have passed in your entire life.

Hell, my ride to work with GPS and cell, and my droid playing a movie
is a bigger datagram than anything you ever fucking did.

And THEN, the guys I work for and strive to give more, better, and
faster data to EACH get a bigger datagram than an old fuck like you was
ever worth.

Remember what I said about your mother? Now, go back and read your
first response to me, and discover why it is that YOU are the uncivil
fucking bastard in this thread. You don't get to live in both worlds at
your fucking leisure, and at my expense boy.

You mouthed off, and you got it back in your face. YOU are still the
primary offender, and YOU will never change that fact.

Why are you so angry? You've been cursing and ranting here all day,
flailing at everyone.

This isn't healthy. All that anger will wreck your immune system and
make you old fast. You'll stroke out eventually, and not have much fun
meanwhile. Really.

You are too goddamned blind to see WHERE the problem is located.

I have been telling you all there is a problem for years!

Were I to say "Are you all ready to be nice now?" there are always six
or eight who still want to take jabs, and then it ensues again.

You getting it yet?

If you all want to be nice, we can do that, but you can bet someone
will start again, and THEN I will reciprocate. I play by those rules of
engagement. That is why YOU got schmacked. Because you are on the
stupid, snide remark bandwagon too. Character compromises shall not
pass.

So, get started on *them* as well.. and yourself, Jeffy Fixit. Every
time I try to be like anyone else, an army of idiots start with their
sub-Jr High mentality horseshit. They will get their plates of shit back
in their faces. Don't you go thinking you can start feeding me one too,
boy. And then some dope thinks that because I cuss, I am wrong from the
start. That is pretty stupid too. Call them "colorful metaphors".

I have the entire archive. Nearly two decades. The names these idiots
use to refer to me with do not match any I have ever used. They can have
that back in their faces. Cussing doesn't mean a fucking thing. You
getting it yet?

I can chronicle every time each asshole started it, from over a decade
ago in some cases.

Good story. It brought to mind a promotional video I saw for a company that
had a process called explosive bonding (of dissimilar metals). They must
have been too cheap to rent lights, so they did the demo outside on an old
wooden table. It was two guys in overalls and, I swear, they could have
retitled it "Gomer and Bubba Find Some Dynamite" and nobody would have
noticed.

Wait until they pull your son over, and then there are five cruisers,
complete with their ss dogs, doing their piggery shake down.

You are the one who has no idea.

Over 50 folks a year die in the US alone. The numbers around the world
are greater still.

They get trained to NOT aim at the chest area, but guess where the
dumbfucks all aim.

Did you see the PIT 'stop' down in Fla earlier last year where they had
like 4 dudes in the car, and the driver got like 3 tasers, and each
occupant got a couple each, and they ran out of tasers before they could
taze the fourth guy? Did you see that video?

Did you see the whole line of cars that were in the left turn lane that
the PITed car slammed into the last one as it rotated and stopped?

The band of pigs that endangered the public that day arrested that guy
like the jack jawed jackasses they are too. Do you know why?

In medical I tend to push the envelope and so do the standards
committees. Sometimes based on what we do. I designed all my cardiac
stuff defibrillator-proof, always, although it was not the law yet. Then
they made it law, because it makes sense.

Believe it or not but I like to have to meet specs in medical because
they protect people. Including you.

> ... Would you like to pay

Out here we do not pay extra. Our cable companies out tend do use modern
technology, not cheap stuff from the 70's. A cable company that isn't

competent enough to do more than a measly 100ft would lose their
franchise rather quickly.

Oh, that's right. You're too cheap to even have cable TV.

Read more carefully. I said TV doesn't matter to us, it is not about cost.

Sorry Jeff but I never used my connectors to support my cables. You may be right but completely irrelevant to me. To me F connector and good connection shouldn't even be used in the same sentence. They are what that are, cheap connectors at best that uses the center conductor of the cable for a contact. Now that is Yech. Heat shrink has nothing to do with the pull test or hiding poor workmanship but it does help keep corrosion down which is the biggest problem with F connectors. Ive never seen one pull apart except in the shoddiest of installations. One of the best things I have found to insure you maintain a good connection is to apply something like DeOxit to the connectors when you assemble them. Best done while all the parts are new.

You are correct that the problem is in the hex crimp and part of this is because they started making the crimp made on to the connector. The other part is that you have to have a special tool to crimp them. All the pictures that you showed are require a special crimp tool. If these tools are worn or dont fit the particular plug/ cable combination you will get a bad crimp. The old style that is probably 40 years old now that you could crimp the little ring with a pair of pliers worked the best. Unfortunately you can no longer get them, well I do have a few.

There little wrong with good quality F-connectors. They are generally
good enough for what they were intended for. Problems are usually down
to who installs them, and how.

For personal outdoor use, I always give any connectors a squirt of WD40
- both during and after installation. [I guess DeOxit would be similar
or better.] After cleaning off most of the WD40, I then seal with
self-amalgamating tape. Obviously, heatshrink would be better, but for
me, is usually less convenient.

Mechanically, even screw-on Fs can be hard to dislodge, provided just
the right amount of braid is trapped under the screw thread. However, I
suppose that sometimes they might not provide the ultimate in screening.

In the UK, in the large CATV networks, crimped connectors are well and
truly a thing of the past. Anyone using them (even the good ones) would
be liable to be hung, drawn and quartered, and then severely punished.

The standard connector is of the 'Snap and Seal' type (and similar). In
themselves, these are pretty well watertight, and the screening is
excellent. It should be almost impossible to pull one off the cable.

However, it is unusual for F-connections to appear naked in the open
air. The final RF distribution to the home is invariably from a street
cabinet which houses an optical node or an RF distribution / line
extender amplifier feeding a bank of taps/splitters. The 'traditional'
cascade of in-line taps has not been used for a very long time. Under
these relatively benign conditions, the F-connectors probably suffer
much less from corrosion than those used on taps hanging on aerial
messenger wires, USA-style. Nevertheless, there are various purpose-made
short 'chunky' rubber sleeves which can be installed first on the tap
ports before the cable connectors are screwed on. These seal the screw

threads. Personally, I would have liked to have seen a bit of WD40 used
but I never managed to drum up much enthusiasm for this as an approved
practice.

No. I know for a fact that paddles were applied while a system of ours
was connected. The doc should have first pulled the plug as the
procedure calls for, but didn't. The witnessing engineer almost froze
but the patient interface held. If it hadn't someone would most likely
have died. I had designed it defibrillator-proof even though the
standard did not (yet) require this.

> You discounting standards in other areas is casual lameness, ...

Like where? And what particular standard? Quote, please.

No, you do not. I was 12 years old, and the gear was my dad's. You
have nothing, and you know nothing. All you do is presume, and you
presume wrong, boy.

The antennas I work with now are everything from 18 foot diameter
gateway heads to yagis for the military that we get in 20 foot long
crates that put anything you ever worked with to shame.

You should go see someone for that multiple personality disorder you
are sporting there, "we" boy. More like "wee boy".

> I suppose Giant Rat of

The short review in Feb 2006 QST says:

According to Comet, the matching circuit is basically a network
of resistors and capacitors. A toroid balun is present as well.

It also says:

The CHA-250B's performance is mediocre
to poor on 80, 40 and 30 meters, but it does
an adequate job on the other bands. At a list
price of $469, this is hardly an inexpensive
antenna. Frankly, a small antenna tuner, a
length of 450-Ω ladder line and a wire dipole
will yield superior performance at less than
half the price.

But:

In circumstances where choices are extremely
limited and cost isn't a major consideration,
the Comet CHA-250B may be a contender,
especially if the alternative is not getting on
the air at all. In addition, the CHA-250B may
also be a viable option in emergencies when
you need a multiband HF antenna that can be
deployed in a matter of minutes. In those situations
you just want to get a signal on the air,
not work the world.

You do it because they wouldn't hire you if you couldn't meet specs,
just like every other consultant, engineer or tech. They might even
jail you for your incompetence for not meeting the specs.

> Believe it or not but I like to have to meet specs in medical because
> they protect people. Including you.

Believe it or not, most technical people have that same standard.
You're nothing special.

> franchise rather quickly.

Once again the all knowing Jeorge shows his ignorance.

1: You don't know what you're talking about, about the cost of service. Any extra operating costs become part of the basic service that everyone pays. You won't work for nothing, and the utilities don't give them free electricity. The service companies don't repair the equipment for free. Do you have any idea how many amplifiers, taps and set top boxes are needed for 10,000 active ports? To provide hotter ports require more amplifiers, and raises the system noise floor. You 'designed an amplifier'. Big deal. A lot of engineers 'designed and amplifier' and those companies are long out of business. Current CATV amplifiers use hybrids designed specifically for the application and they use them for many reasons. That just leave the design of the 60V modified sine wave to DC power supplies, equalizers, gain control, equalization and remote switching. Some locations also have remote monitoring so the headend can check system status on a continuous basis. It can also report outages when some of the equipment doesn't respond. They can even detect power failures and monitor the battery status in the standby power supplies to give them time to get a portable generator to the area if it is an extended outage. The local Brighthouse system remained in operation here for over four weeks after a hurricane even though the only way to watch TV or access broadband was with battery power or a generator.

2: '70s CATV tech was 12 channel with no return path. It was crude, discrete point to point designs that looked like a ham put together from junk TVs while drinking cheap beer. They were touchy as hell, their tempco sucked, and they were impossible to service without a fully equipped test bed. the power supplies were simple, poorly regulated linear supplies with 85 C electrolytics that died quickly in the southern sun. The large diecast aluminum housing ran hot to the touch without the sun hitting them. That stuff was pretty well all scrapped out by the mid to late '80s by 36 or more channels with return capability. There was so much construction of upgraded systems that there was a severe shortage of new hardware through most of the mid '80s.

That '80s tech was gone in all but the smallest systems by 2000. Today most systems are 450 MHz or higher, and are 'Fiber Enhanced' to provide telephone, broadband, movies on demand and pay per view services by breaking the system into cells that cover a few hundred homes, or

less.

3: You know nothing about CATV franchises. 'A measly 100 feet' is
more than adequate for a hell of a lot of drops & house wiring. If that
is what the franchise calls for, THAT IS THE SPECIFICATION, no matter
how much you whine like Sloman. A city or county won't pull a franchise
over one or two people complaining about weak signals. They receive a
fixed percentage of the system revenue every month, and the percentage
was set when the economy was up. If they pull the franchise, another
provider will offer a much lower percentage. It also involves legal
fees, and causes the rates to go up for the users. Why put up with all
that for a fraction of a percent of problems. Like people who built a
private road a mile long and want to pay the standard install fee when
it will cost about $15,000 to run a feeder for that one house. Or like
that marina. It isn't a street. It's private property. If they want
better service, let them pay for upgrades with .500 cable to each boat,
with a .500 to 'F" connector for each boat. That would only cost a few
hundred dollars a boat for materials. More if the cable is jacketed.
If it isn't it won't last long in salt air. Double that for the
hardware and labor to get a good idea of the costs.

> Oh, that's right. You're too cheap to even have cable TV.
>
> Read more carefully. I said TV doesn't matter to us, it is not about cost.

Then why are you being such an ignorant prick about the issue when
you have no horse in the race? You sound more like Dimbulb every day.
I used to think highly of you, but no longer

You didn't need heat shrink on good 'F' connectors.

Not needed, if you use flooded outdoor cable.

A 'special tool' that only cost about $20 and would do thousands of
crimps before it was worn out. I've bought them new, on sale for $8
US. You admitted to using pliers on the cheap crap, and you certainly
can't do that with a hex crimp.

Umm... you've never tripped over a cable, had the equipment fall off the table with the cables attached, run RG6a/u up a pole to where it has to support its own weight, moved furniture with cables still attached, flexed the connector when used as a test lead, pulled cable through the wall or conduit with connectors attached, etc? These are all very common situations which will stress the connector to cable connection. While it might not be a problem for a fixed (stapled in place) installation, it certainly will be a problem for the average home user.
<http://802.11junk.com/jeffl/pics/drivel/slides/mess01.html>

I find it odd that outdoor CATV uses quad shielded cable to prevent RF leakage and ingress, and having the cable swept to perfection, while you recommend using inferior F connectors.

>To me F connector and
>good connection shouldn't even be used in the same sentence. They are
>what that are, cheap connectors at best that uses the center conductor
>of the cable for a contact. Now that is Yech.

I do have some issues with RG6a/u that uses copper plated steel core center wire. Mostly, it's a corrosion problem for outdoor connections where the home owner does their own wiring, and uses F connectors without the necessary rubber o-ring needed for waterproofing. I've swept F connectors on the bench and find them quite good and often superior to the rare 75 ohm TNC and BNC connectors near the top end (2GHz for satellite). Incidentally, most of the antennas (that survived a recent storm) on my roof use RG6a/u coax. The mismatch loss between 50 and 75 ohms is minimal. Some use F connectors, but most use BNC's made for RG6a/u.

>Heat shrink has nothing
>to do with the pull test or hiding poor workmanship but it does help
>keep corrosion down which is the biggest problem with F connectors.

Ahem. I worked for a marine radio company during the 1970's. I learned a few things about waterproofing and corrosion. Heat shrink doesn't work. Capillary action along the heat shrink to connector boundary will suck the water into the connector.

What I use (when needed) is a layer of 1" PTFE tape (or 1/2" if that's all I can find) over the connector. Once in place, a layer of Scotch 66 or other electrical tape to hold it in place. The PTFE will cold flow into the irregularities on the connector surface, and there will be zero capillary action. If I want UV resistance, I spray the tape with clear Krlyon (acrylic) spray.

While we're on the topic, I've experimented with various allegedly waterproof enclosures and packages. The only ones I consider genuinely waterproof are sealed and pressurized with dry air. Anything less will eventually leak.

>Ive never seen one pull apart except in the shoddiest of
>installations.

I have and all too often. I was at the neighbors trying to troubleshoot their Comcast cable tv and modem mess. They had some friend of theirs do the wiring. All the F connectors were crimp ring type and were falling apart. The coax was mostly RG-59 with maybe 80% coverage. I replaced the most disgusting and will finish the job when I have time.

>One of the best things I have found to insure you
>maintain a good connection is to apply something like DeOxit to the
>connectors when you assemble them. Best done while all the parts are
>new.

DeOxit and Cramolin contain oleic acid, which will slightly corrode copper. It's good for CLEANING connectors by removing the oxides, but should not be left on the connector. If you want to make sure that you can take the connector apart after the threads rot in place due to galvanic action between the aluminum receptacle, and the nickel plated crimp type F connector, some silicon or lithium grease would probably be better.

Some notes on the contents:
<http://www.antiqueradios.com/forums/viewtopic.php?t=82058&start=40&sid=71ca160c8f607686916a0f355e9ecc34>

>Jimmie

As for special tools, I love them. My various cable preparation tools for various coax cable have saved me countless hours of fumbling with a pocket knife and diagonal cutters. Using the various compression tools on F connectors almost guarantee a good connection, unless I did something dumb. Same with crimp lugs, various LMR-xxx coax cables, and Anderson Power Pole connectors. The days of using a hammer or vice grips to crimp a connector are over. The cost can be substantial, but is well worth it if you work with connectors regularly.

Correct. And the spec for a competent cable company is typically 300ft,
as I have shown in the link. Plus the one below.

>
>> Believe it or not but I like to have to meet specs in medical because

>

Never said I was. Except that I do exceed standards at times where I
believe it is necessary. In the case of med electronics that has likely
saved lives. I do not subscribe to the idea that a standard is always
good enough. Because sometimes they are not.

>
> Once again the all knowing Jeorge shows his ignorance.
>

No. I suppose you know what MoCA is. Do you consider them ignorant?
Because they say the very same thing that I said. What matters is
today's state-of-the-art. Nobody cares about what it was in the 80's.
Today this is state-of-the-art:

http://www.cablefax.com/ct/sections/features/Testing-And-Deployment-Making-MoCA-In-Home-Ne
tworking-Easier_44237.html

Quote "The Multimedia Over Coax Alliance (MoCA) provides a standard ..."

then

Quote "The maximum cable distance supported between the root and the
last outlet is 300 feet, with a maximum attenuation of 25 dB". And this
is for MoCA, not just cable TV.

So how many linear RF amplifiers above 1W have you personally designed
and guided through layout?

Hint: All my clients are still in business and I am sure will be for a
long time to come.

No, it is not. If you don't believe me check out Cameron Park, CA,
especially the area of the Estates. Then tell me how you want to do that
with 100ft drops.

> ... If that
> is what the franchise calls for, THAT IS THE SPECIFICATION, ...

And the franchise would get kicked out of the market around here. You can't serve this market with a sub-par spec. The big automotive companies had once exhibited a "Well, this is the spec and that's that" attitude like you do in this thread. Then they learned, the hard way. In part by essentially going on welfare which was embarrassing.

> ... no matter
> how much you whine like Sloman. A city or county won't pull a franchise
> over one or two people complaining about weak signals. ...

They will if there's a whole big crowd showing up at the next meeting. Now I won't because I only watch the evening news via antenna. But I know a whole lot of folks who would be miffed to be declined service because they are literally addicted to the sports channels. Many would just get satellite though, they market that quite aggressively these days.

> ... They receive a
> fixed percentage of the system revenue every month, and the percentage
> was set when the economy was up. If they pull the franchise, another
> provider will offer a much lower percentage. It also involves legal
> fees, and causes the rates to go up for the users.

The county folks have one much more important thing on their mind: How to get re-elected. That's what'll matter most to them. They know that seeing complaints about what many people perceive as a utility service they have "rights to" in the paper is not the way to get re-elected.

> ... Why put up with all
> that for a fraction of a percent of problems. Like people who built a

> If it isn't it won't last long in salt air. Double that for the
> hardware and labor to get a good idea of the costs.
>

Then answer a question I asked you before but you did not comment on it: Why did Mike's cable provider not decline service? Obviously it worked reliably in the analog days and now with DTV it doesn't. If they can't handle the 170ft drop after the digital switch, why did they not inform Mike, cancel the service on their part and send someone out to pick up the set-top box?

The short review in Feb 2006 QST says:

According to Comet, the matching circuit is basically a network
of resistors and capacitors. A toroid balun is present as well.

It also says:

The CHA-250B’s performance is mediocre
to poor on 80, 40 and 30 meters, but it does
an adequate job on the other bands. At a list
price of $469, this is hardly an inexpensive
antenna. Frankly, a small antenna tuner, a
length of 450-Ù ladder line and a wire dipole
will yield superior performance at less than
half the price.

But:

In circumstances where choices are extremely
limited and cost isn’t a major consideration,
the Comet CHA-250B may be a contender,
especially if the alternative is not getting on
the air at all. In addition, the CHA-250B may
also be a viable option in emergencies when
you need a multiband HF antenna that can be
deployed in a matter of minutes. In those situations
you just want to get a signal on the air,
not work the world.

I'm somewhat skeptical of the claims at lower frequencies, particularly with
my recent experiments with tuner loaded verticals.

The current experiment is a 14 foot long vertical (on a flat metal roof) fed
with 25 feet of RG-8 and a tuner at the rig. It does work quite well on

20-10 meters, but not below 20 meters.

I saw a case of that twenty years ago in Key West, Florida. I suspect the authorities had to look the other way because affordable technology to do it better didn't exist. The Florida Keys were served out of a headend that was close enough to the mainland to get decent OTA signals. however, by the time those Miami signals got to Key West, they were pretty bad. I have no idea how many amps were used. (IIRC, local origination channels were OK.)

I think five amps is about the limit due to added noise and cross-mod.

In practice, without serious and constant TLC, the length of cascades of
amplifiers is usually limited by the frequency response flatness (or
lack of it), and the ability to maintain it. I think that the maximum
I've been involved with was a cascade of about 20 normal trunk
amplifiers plus three or four distribution amps / line extenders on the
end. Thank heavens these days for optical.

The tuner for short antennas should be at the antenna. While it will not be
a real killer of a signal, many mobiles do very well with antennas about
half that long, but the antenna is usually loaded at it to match the
feedline.
If you put one of the screwdriver type antennas in the same spot, it shuold
make a lot of differance on the lower bands.

Not mentioned in my previous post is that there is a separate vertical 11
feet long, base loaded, for 40 and 30. I haven't really done much
experimentation with it yet.

I am interested in knowing more details about the Comet matching unit, but I
suspect that the details are unavailable.

Yep.. My mobile antenna in it's longest "parked" config is a 14 foot
tall whip, and the loading coil is at 8 or so feet up from the base.
It browns the food quite well on 80 and 40, mounted on my large Ford
truck.
The base of the antenna is on the side window pillar, about 2 feet
below the roof line.
I've parked on the beach "Gulf Coast" and done better on 1500+ mile
paths with 100w than some of the guys running dipoles and amps at
various home stations around the country.
No joke.. just due to my antenna spitting most of it's power at just
the right angle, where as theirs were largely aiming straight up in many
cases.
Anyway, the loading is the key.. If the 14 foot whip is loaded at the
antenna, and the radial system is good, it will work pretty well.
And as usual, it's better to have the coil center loaded or slightly
higher for best results. Or add a top hat/wires. But that may cause
```

visual issues for some. :|
But even base loading would work much better than tuning from the shack
with a tuner. On the low bands with a such a short whip, the tuner loss
will usually get you, even if the feeder losses are low.

No one has a 'right to' cable TV. I was at one meeting where a
citizen was demanding that they revoke our franchise. They told him
that one complaint out of 10,000 customers wasn't enough reason to
revoke. he was as arrogant as you. Everything had to be his way. He
got really pissed when they told him to buy a satellite dish and go
away. His demand was a s ignorant as yours. He was demanding that he
bring back CBS ARTS, and wouldn't listen that CBS had dropped the
service. One other complaint was from a woman demanding that our
franchise be pulled because CSPAN was down for a couple days during the
modification of a 5 meter dish to multiple feeds.

Sigh. Just because there is a new agreement for the industry doesn't
mean that all existing have to comply. Some companies are FIOS. By your
standards, everything else should be replaced overnight. Then the
distance won't matter at all. I doubt that the income from that marina
will ever pay back the construction costs. the system worked for
analog, when it was installed. There are no guarantees in life. Stop
trying to walk on water, you'll drown.

From the beach at Port Aransas TX, I connected a 20m dipole to my 100W TS-120. The dipole was 9 feet up in the center (ladder on the motor home) and the ends were about 5 feet off the dirt. I worked three German stations in short order, along with a slew of guys in the northern US. (The Germans were contesting that weekend.)

You just never know what will work.

I wrote some notes at http://vk1od.net/antenna/misc/CHA250.htm .

The advice that it contains resistors is not supported by inspection of the device.

It is lossy, and loss is a common technique for broadbanding an antenna system.

If you Google, you should find plenty of pics of what is inside the base of the unit.

MoCA is home networking, hence the 300 foot figure. A drop at +10 dBmv already allows a 25 dB loss for the cable modem, since they are designed to work to -15 dBmv. That webpage also mentions verifing that a "drop amplifier does not block Moca". In other words, it's home networking for multimedia devices and has nothing to do with the length of the cable drop. It is to allow customers to stream audio and video within their home, and use services like Netflix & Hulu on their TV sets.

I bet that all the stations gave you a 5x9 report also.

Go to a country that is on the rare list and you can put up a wet piece of string and get 5x9 all day long no mater how many times you have to repeat the calls.

During good conditions almost anything will work. It is under bad conditions that a beter antenna system pays off. I have a beam up 60 feet and some wire antennas around the same height. Most of the time the signal levels are such that I can hear the same stations off either one. There are times that I work stations off the beam with good received signals that I can not even hear on the wire antennas.

Where do you live? The parts of FL I have seen were are technologically advanced, I guess. This stuff is rolled out here in CA, big time. Things like the DCX3200M box and their DVR are MoCA.

In case you've missed it, MoCA has already release 2.0. More than a year ago ...

It is the modern cable TV, like it or not. Companies not playing will
likely be packing some day. Personally I doubt it'll do much for home
networking, at least not appliance control. Computing, yes, and that's
the new game in town. Cable companies offering "all-in-one" packages
where you get phone, Internet, TV and all that from the "company store".
Pretty pricey, last time I looked it was $99/mo and that only for the
first year. Probably goes up afterwards.

Hi Jeff,
I don't seem to be able to follow your directions, I don't think I
have enough buttons. To get the info I posted, Push and hold the power
button until the power light blinks, then push power again and the info
screen comes up.
I don't know what the MAIL light is, I don't have a select button nor
a INFO button.
Hey started pushing buttons on the remote, found I can scroll through
15 pages off stuuf I don't have a clue about.

Got some "RF Statistics on page 5"
Current FDC
Freq. 75.250
Level 5 dbmv
S/N 29db
Errs/Ave 0/0

Current Qam
Freq. 513 Mhz
Level -1dbmv
S/N 35db
Errs/Ave 11/0 or 11/1 or 11/3 but mostly 11/0

That's all I can see.
Mikek

Sigh. You never back down, even when you are shown that you are
wrong. You are wrong and it's eating you alive. Even the title of the
article in your link states: "Testing And Deployment: Making MoCA
In-Home Networking Easier" and the article starts with: "Market growth
and competition for enhanced video services revenue have MSOs and telcos
scrambling for technology and operational advantages. In the next
decade, consumer electronics with embedded Internet and IP video support
will be widely available." No where does it mention a cable drop. It
is a method to transmit digital data between a DVR and any TV connected
to the system. Nothing more. It's no wonder you can't get a computer
to run properly, when you can't even read a simple networking article
like this and understand it.

Show me anywhere in that article that states a 300 foot cable TV drop
is required. The word drop shows up twice and the first is part of
another word:

1: "Additionally, the technician can monitor the MoCA channel for
bit errors based on corrected or dropped MoCA packets."
^^^^

2: "A drop amplifier that does not bypass the MoCA spectrum."
^^^^
This means that some installations require a bi-directional amplifier
to compensate for long drops just as they always have. 'Drop Amplifier'
refers to a single output CATV amplifier as opposed to the multiport
CATV distribution amplifiers used in apartment complexes and condos.

> Companies not playing will likely be packing some day.

Maybe in 30 years, when tiny rural systems can't find anything
cheaper on the market and upgrade in bits and pieces. YOU know all
about being a cheapskate.

> Personally I doubt it'll do much for home networking, at least
> least not appliance control.

Why should it? Why would your DVR need to talk to your
refrigerator? It is strictly a streaming system for home
Entertainment. It's been available here, for years. Hell, even my
dad's Direct TV sat system w/DVR does it. Appliances don't need a TV
tuner and other crap for a simple ethernet interface.

Computing, yes, and that's the new game in town. Cable companies
> offering "all-in-one" packages where you get phone, Internet, TV
> and all that from the "company store".

Phone and internet are delivered via a cable modem that works to -15
dBmv.

> Pretty pricey, last time I looked it was $99/mo and that only for the
> first year. Probably goes up afterwards.

It goes a hell of a lot higher than that. That $99 doesn't get you
basic cable, internet and phone here. Add on more tiers and hgher
bandwith internet and it can pass $250 a month.

You are so ignorant that it's scary. Read ALL of the page you linked
to and look at the images. It is a lousy home network via coax
streaming media standard and nothing more. Not that I ever expect you
to be man enough to admit you are wrong. Everything is always someone
else's fault. No one ever does anything right but you. The fact that
you design medical electronics scares the hell out of me.

It shows that you have a 6 dB slope, and the high end is 1 dBmv below the standard level. It also shows a lot of errors in the recovered data. QAM is the digital TV signal. Unscrambled channels are referred to as Clear QAM

Probably not an explicit resistor, but some sort of network that is really lossy and has the same effect. There's a variety of this sort of thing around. Radio Shack used to sell a wideband vertical with a funky looking ferrite transformer. Looking up the patent, you could get the schematic, and basically, it was a 10-15 dB loss over a pretty broad band. Not too tough to get a 1.6:1 SWR with a 15dB pad in the system (in fact, I'd be amazed if the SWR was ever as bad as 1.6:1)

The odd thing is, such things DO work. When propagation is hot, an extra 10-15 dB of loss isn't even noticeable.

Presumably 75.25MHz is an analogue signal? In the UK, at least while the cable system has carried a mixture of analogues and digitals, the digitals have been run 10dB below the analogues. If 75.25MHz had been digital, it would be set at -5dBmV, so there would be a rising slope of 4dB, LF to HF.

In any case, if the 513MHz digital is -1dBmV, and other HF signals are similar, that is more than sufficient for a digital set-top box. I would think it should work reliably down to around -15dBmV. If I'm right, whatever the problem is, it isn't being caused by a lack of signal level.

:-)

But it's everywhere. Here is an example from South Carolina about what
happens when a company wants to push through a sub-par 125ft and the
city insists state-of-the-art 300ft:

http://www.redorbit.com/news/technology/329657/orangeburg_city_council_adopted_franchise_without_cable_company_agreement/

They threatened to not renew the franchise. And this was six years ago.

At night, my mobile antenna was usually better than my home dipole
on a path from TX to FL. "40m" I discovered this after talking to a
guy from the car, and then switching to the dipole when I got home.
My signal dropped. :(And it was no fluke. I tried it several
more times, and the mobile won most every time.

It's just the mobile antenna being better at that lower angle,
than the dipole, which at 35 feet or so, probably was better for
NVIS, than longer paths.
Of course, in the daytime, the dipole smoked the vertical on
all the shorter paths.
But I've never had any trouble being able to operate running
mobile on 80 or 40 meters. Even the short regional paths on 80m,
I was always able to work the people I wanted to. Often with
quite decent reports for a mobile in a NVIS world.
Would be quite normal to get reports of 20+ DB over 9 on most
peoples meters. Sometimes 30 over 9. And that's on a fairly short
80m path of less than 500 miles.
My mobile antenna in the "driving config" is 11 feet tall.
It's about 5 feet under the coil, and 5 feet above it. The
coil itself, being about a foot.
I add a 3 foot solid hustler mast to make it 14 feet when
I'm parked. Then, it's 8 feet under the coil, and 5 over it.
Makes quite a difference.
But I'm only set up to use those on my trucks now.
I still have not been able to bring myself to cut holes
in my newer Toyota.. :(I know if I do, it's eventually going to
warp the trunk lid, like it did when I mounted it on an Honda Accord
I had. Even with reinforcing under the trunk lid, it eventually
slightly warped the area around the hole. And this is with a
light mostly glass antenna. Mine is a "plastic bugcatcher". :|
So with the Toyota, I just go without, and just take the radio
to use when I get where I'm going.

Agreed. I only operated from that beach for a few hours on one day. The
next day might have been terrible.

When propagation is hot, an
extra 10-15 dB of loss isn't even noticeable.

Like 10m today. Path from Florida to West Coast was like a land line around
1900Z.

Failure to maintain eye contact with the audience indicates several
possible problems. In this case, my guess is that he's totally unsure
of himself. Test antennas in a Faraday cage? The audio track is
probably good enough to run a voice stress analysis lie detector, but
it's late, and I'm tired.

I can guess where he got that idea.

* Kulrod technology: only by larsen.
All Larsen antenna whips feature the exclusive Kulrod plating
system to assure superior performance. This consists of 3 plated
(Copper, Nickel, Chrome) which allows an increment of its
radiation capacity and reception signal and avoiding overheat.

The problem is that the skin depth at VHF/UHF frequencies, the skin
depth is less than 1 micron, which is much less than the probably
20-50 micron plating thickness of the various layers. However, if the
skin depth did go through multiple layers, the dissimilar metals might
cause PIM (passive intermod):
<http://www.rfcafe.com/references/calculators/skin-depth-calculator.htm>
Never mind that all decorative chrome plating is over layers copper
and nickel, in order to get decent adhesion. See "Decorative Chrome
Plating" section:
<http://www.finishing.com/faqs/chrome.html>

Since the CEO says that technology was "accidentally" discovered, I
can also suspect that aliens were involved in the technology transfer.

> >must serve you. This is state-of-the-art. Now you'll probably declare
> >the whole State of Vermont to be wrong?
>
> The whole state? Na, there's probably three sane people left.

The FCC says the requirement is 100 feet in CFR 47-46.606, section three, quoted below:
---
(3) The visual signal level, across a terminating impedance which correctly matches the internal impedance of the cable system as viewed from the subscriber terminal, shall not be less than 1 millivolt across an internal impedance of 75 ohms (0 dBmV). Additionally, as measured at the end of a 30 meter (100 foot) cable drop that is connected to the subscriber tap, it shall not be less than 1.41 millivolts across an internal impedance of 75 ohms (+3 dBmV). (At other impedance values, the minimum visual signal level, as viewed from the subscriber terminal, shall be the square root of 0.0133 (Z) millivolts and, as measured at the end of a 30 meter (100 foot) cable drop that is connected to the subscriber tap, shall be 2 times the square root of 0.00662(Z) millivolts, where Z is the appropriate impedance value.)

That mess in Vermont involves Adelphia cable, and the settlement of a huge fraud lawsuit. They agreed to build to a minimum of 14 homes per mile, when the industry usually stops at 35-40 homes per mile as ever paying back the construction costs. Vermont had them by the balls, if they wanted to renew their franchisee. Adelphia is also heavily invested in FIOS.

The other franchises I looked at only had a 300 foot limit if it was Fiber to the structure, which doesn't have the roll off and insertion loss of coax.

Here is a typical RG6 from Belden:

Freq. (MHz) Attenuation (dB/100 ft.)
5 .67
55 1.60
211 2.87
270 3.24
300 3.43
350 3.72
400 4.00
450 4.26
550 4.71
750 5.59
870 6.00
1000 6.54

This shows the loss at 12.78 dB at 450 MHz which would be a very old system.

Last year, I bought a Larsen 2/70 antenna and mag mount base.
I couldn't figure out why it didn't radiate all that well.
Got home and looked at the antenna.
Said to myself - you dummy - you didn't remove the paint from the base portion of the whip.

Even with the screw tightened to the point of where it made a dimple in the whip - it still was not making good contact.

I put it on the wire wheel, removed the paint, put some Nolox down in the hole and tightened with the allen wrench and have had no problems since.

To date - my best hill-topping was about 100 miles on 2 meters and 440 in the hills of Pennsylvania.

Even at that - the mag mount is a poor conductor - because there is a rubber pad over the magnet and you cannot get a good bond to the vehicle body unless you remove the paint under the magnet and the rubber insulator.

I Went to a Ham Fest last year and saw a couple of the antenna parts for a couple of dollars each and like a dummy didn't buy them.

If you have the magnet mount and the loading coil - you can use any old antenna you want. Just cut it to length and stick it in the hole.

As far as getting rid of what I have, because something better came along.
Antenna technology peaked about 1971 when the CB radio was the fad.
In those days if you wanted a decent antenna for a decent price - there was enough manufacturers out there to take your money that you didn't have to look or travel far to find them.

When the accountants took over the antenna business, it wasn't long before the quality went away and the big beam antenna's were replaced by cheaper - less efficient models that were more profit friendly to the manufacturer.

You can only sell a $100 antenna for so long before you either have to ask your employee's to take a cut in pay, or you ask the engineers to find a way to make it cheaper.

Mobile antenna's are no different.

Hello, all, and I watched the entire video from Chamtech. There have been many firms over the years attempting to develop conformal antennas (primarily for military/shipboard use) that were supposed to either equal or exceed the performance of conventional antenna designs in the operating frequency range. This is the first "spray-on" one I've seen. As for the Chamtech presentation:

1. Since when do antennas on police cars get hot to the touch?

2. It seems clear the presenter is a marketer with scant knowledge of antennas/electromagnetic theory. IOW ignorant of the underlying basic physics (which can also apply to Hams, sadly). If Chamtech's technology actually works, it won't be due to the mechanism(s) claimed.

3. Dubious operating range performance claims, especially in a submerged environment (I sure would've like to have been present for the underwater tests.)

4. All this reminds me of the crossed-field antenna (CFA) saga.
Sincerely, and 73s from N4GGO,

My guess(tm), is that the coax cable between the radios and the
submerged antenna was doing the radiating. At 50MHz, the leakage from
3 watts of tx power should be sufficient to get 3 miles.

Losing touch with the other end of the link is predicatable. At 6ft
above the water, the visual horizon is 3 miles away.

The picture of the submerged antenna seems to be a biquad antenna,
which looks much too small for 50MHz. Each loop would need to be 1
wavelength long or about 30ft circumference. See 8:25 minutes into
the video.

indeed..

Or, maybe, since it's a misunderstood but actually functional
technology, the one where a stream of salty water passes through a
suitable coupling network. Lame, but works. Better than the CFA.

The alien visitation theory is mine. My logic is that since the
technology was "accidentally" discovered, and since the CEO is
obviously lacking in scientific expertise, there can be only one
possible remaining source for the technology. It came from outer
space, handed down by an advanced civilization. When obvious sources
of the information do not lead to a generally acceptable consensus,
the traditional default explanation is advanced alien knowledge
delivered by flying saucer.

I don't think it's the green card aliens that are processing nano
capacitors into antennas. Their level of expertise and technology is
usually lacking. The H1B visa visitors might be a better possibility.
However, most of those are smart enough to recognize a profitable
technology and will usually prefer to take it back home with them.

Got it.

It's apparent they know a few things about spraying.

430. Homebrew or Copycat B&W AP10 Windowsill Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2012-02-16 02:44:31 UTC
From: Irv Finkleman <finkirv@shaw.ca>
Message-ID: <n4__q.23$2q1.16@newsfe06.iad>

Somewhere I recall seeing an article on homebrewing a windowsill antenna similar to the B&W AP-10. Does anyone have a copy they could email me, or a link where I can find the information. I was hospitalized for serious problems and all my ham gear including many books were donated to the local ham club -- I'm starting again from scratch after 54 years of hamming, but on a much smaller scale!

Thanks for any assistance in this matter.

I don't know of a specific article, but

http://www.bwantennas.com/instr/Ap10b.pdf

is the instruction sheet for the final version of the antenna. Page 2
shows a fairly decent physical diagram of the antenna coil
construction.

Basically, the antenna appears to be a telescoping whip, with a large
air-core inductor / loading coil mounted below it. A flying lead is
used to short out some of the turns on the coil, in order to set the
amount of inductance. A variable-length counterpoise wire is used;
both the counterpoise length and the loading-coil fly lead setting
must be adjusted for each band in order to get a good match.

You could probably either use a piece of Airdux inductor stock, if you
can find one at a hamfest / flea market, or wind your own inductor on
some sort of suitable form (perhaps PVC pipe?).

It looks like a fairly standard "small antenna" approach.

Addition of a small LC tuner at the base (homebrew, variable cap +
recycled roller inductor?) might save you some time during setup and
band changes, by reducing the need to fiddle with the counterpoise
length and position to get a usable impedance match.

Mobilfunkmast aus der Spraydose

Schlechter Netzempfang kï¿½nnte bald schon der Vergangenheit angehï¿½ren.
Das US-Startup Chamtech Enterprises hat auf der Zukunftskonferenz
ï¿½Solve For Xï¿½ von Google die Antenne zum Aufsprï¿½hen vorgestellt.

Das Spray soll groï¿½e, senkrechte Objekte wie Bï¿½ume oder Wï¿½nde durch
simples Besprï¿½hen in Funkmasten verwandeln kï¿½nnen. Organisches
Material in der Sprï¿½hflasche soll dabei verschiedenste Magnet- und
Radiofrequenzfelder, selbst unter Wasser, aufbauen kï¿½nnen. Das
Unternehmen will damit vor allem Mobilfunkunternehmen ansprechen.

Cellphone antenna for sprayers

Vertical objects like trees or walls can be converted to cell phone
antennas by spraying. Organic material will result in electromagnetic
resonating fields even below water

http://blog.ziggytek.com/2012/02/13/chamtech-introduces-low-power-spray-on-antenna/

Hope it's not Scamtech.

w.

<john.wood@nrl.navy.mil> wrote:

>Especially if it was pitched by Billy Mays (R.I.P) ;-) Sincerely,

I got my start in antennas and RF reading Popular Electronics with
advertisements for "Turn your house wiring into a gaint 1000ft TV
antenna". Inside the magic box was a "capacitator". Plus the AC-DC
TV chassis into the wall the wrong way, and sparks would fly. After
getting shocked a few times, I figured that anything that powerful was
worth learning about.
<http://books.google.com/books?id=4NsDAAAAMBAJ&pg=PA33&lpg=PA33>

Roll forward half a century, and I'm still reading (and writing) about
electronic hoaxes (and science fiction business plans). The shocks
are largely gone with the demise of tubes and the introduction of low
voltage transistor devices. I don't miss getting zapped that much.

Additional entertainment. Turn your your house wiring into a
2.4Gbit/sec internet connection. Different names, different
technology, more dollars, but everything else the same:
<http://www.wired.com/wired/archive/9.11/media_pr.html>

Drivel: I had to build a peak audio detector and AGC to reduce the
average TV audio level specifically to keep the Billy Mays commercials
from shaking the house. It sorta worked, but with some side effects.
After he died, I was able to safely remove it.

Don't assume that all nanotech antennas are science fiction. See:
<http://en.wikipedia.org/wiki/Nantenna>
<http://www.inl.gov/pdfs/nantenna.pdf>
These may possibly be the future for solar energy conversion.
The main advantage is the high 85% efficiency, which unfortunately
has yet to be demonstrated. The maximum theoretical efficiency
for a multi-junction type solar cell is about 38%. For a common
single junction, it's about 20% max. The nantenna is basically a
dipole antenna, resonant at light wave frequencies, with a built
in rectifier. Small is beautiful.

However, nanotech solar power doesn't have anything to do with nano
capacitor antenna spray.

I cheated and downloaded it from the ARRL web pile.

When we had our last big earthquake in 1989, most of the damage to my house was done by my magazine collection falling over and flooding the kitchen and hallway. I was walking on top of a 2ft "carpet" of magazines for about a month until I was able to haul them off. As I vaguely recall, the magazines filled 3 heaping small pickup truck loads. After the magazines were cleared, I discovered that their weight had caused the sub-floor to buckle, and pull away from the wall framing. Beware of magazine collectors syndrome. These days, I recycle more often and read online. Much better.

I used to have a b&w ap-10 and it worked quite well. I tuned it by adjusting the length of a single radial across my apartment rug. MFJ makes a window-sill antenna that looks awfully similar: http://www.mfjenterprises.com/Product.php?productid=MFJ-1622

The user manual is online, and you can probably order the little bugcatcher-style coil a la carte.

Not sure if you got my little joke there. In the early seventies
the women were 20 yrs old to today they are 50+, but they look real good
in the magazines for 50+ yr old women... My seventeen year old son was
not happy to see me through them out before he got a chance to peruse.
I have a collection of QST from the 80's in the attic, thinking maybe
I should move them so they are at least sitting over a wall, for support.

Thats a good idea. Ceiling in my daughter's room has a sag in it
because of my mags.

I got my ticket in 1957. I was always collecting junk from others,
By 1982 had accumulated a full collection of QSTs back to the 50's.
I also had all CQs back to the mid 30's, and miscellaneous other
radio mags. I had some 30 ft of shelving in the shack which eventually
collapsed. I didn't need an earthquake! It took a week of
gathering the mags off the floor, going through them all for
articles on antennas mainly, which I clipped and saved,
then disposing of old mags a bagful at
a time in a local unprotected dumpster. No other hams
wanted them.

I think I will rejoin
ARRL -- I left them in '86 for the Canadian Ham organization
mag, but realize now that the ARRL archives are a valuable
source of useful info.

My favorite sport was digging through the dumpster behind Henry Radio
(in Smog Angeles) or various Radio/TV repair shops, for parts and
pieces. I would haul the carcass home on the bus (don't ask) and tear
them apart in my parents garage. These days, I go to garage sales,
thrift shops, flea markets, and buy on eBay. The results and quality
are about the same.

No earthquake required here. Just my lousy job of attaching the
shelving to the drywall and overloading the shelves. Gravity always
wins. It took about a week to clean up the mess and reattach the
shelves.

A clean shop is a sure sign of someone that pays retail:

The ARRL archives QST from December 1915 through December 2007. More
recent issues are not available online.

Well, 12 issues of QST weighs 8.0 lbs and are about 3" thick
(compressed). I had a pile that was 10ft long, about 6ft high, and
two rows deep. Mostly EDN, Electronic Design, RF Design, various
microwave mags, etc. My guess(tm) is that it was about 120 linear ft
of magazines. At 32 lbs per linear foot, that's 3,840 lbs.

Shortly after getting my ticket I spent nearly a year in OKC going to computer school living in a 2 story apartment. To get on the air I use about 15 ft of EMT conduit and built a little LC tuner of scrounged Cu tubing and a cap out of a 5 tube AM radio. Picked up a CB VSWR meter at a yard sale for a tuning indicator. Later picked up an MFJ tuner at a hamfest, wahoo. Balcony railing was my counterpoise.

I spent 26 years in the Navy ('57 to '83) moving from place to
place. Whether onboard ship, in navy Quarters, or after marriage
in apartments and houses, I always managed something similar. Following
retirement I became somewhat of an expert in helping other hams
setting up concealed or low profile stations. I had a marvellous
collection of assorted parts and pieces with which I could easily
throw something together. Two years ago, following a serious
illness, I sold my house and moved into an assisted living facility.
I donated all my ham radio equiment, books, junkbox, and so on
to the local ham club -- a real 50 year old treasure collection
which I wish I had today! I'm well again, or at least well enough
that I'm going back into hamming -- starting from scratch. I'm
really looking forward to being on the air again,
As we say in Calgary, aka Cowtown, Yahooooooooo!

Good for you Irv, and I'm glad you are doing better.
Modest antennas can be fun, particularly when sunspots cooperate!

I'm in a lot more pain lately, and I'm having a harder time
controlling my temper. I am dropping a lot of things, between carpal

Tunnel & nerve damage to my hands. I am also tired of hearing lies from doctors. For some reason, my medication for enlarged prostrate was put on hold for 90 days, and not being able to sleep more than an hour or two at a time is starting to get to me after two months without more than four hours sleep a night. There are days that I want them to cut my damn legs off, to get rid of the constant pain. they hurt when I lay down. They hurt when i get up. They hurt when I'm sitting, and when I'm walking. I have been waiting over a year for the proper surgical support stockings, only to be told a few days ago that it's no longer available. I waited over five years for a pair of diabetic shoes. I couldn't find anything that fit, so I was wearing a pair of old shoes that should have been tossed three years ago. 10 years ago my feet were 8.5 wide. Because of Diabetes and circulation problems, they are now 11 EEEEEE (yes, 6E) and some days I have trouble even getting those on. I have 'Turned the other cheek' so many times that I no longer care.

Sorry. I had it right when I first inscribed it. Then, I made a few
edits and corrections, where I introduced the usual amgiguities and
incoherence.

However, this offers the chance to rant a little. I renewed my ARRL
membership about a month ago. A few days later, the third renewal
notice arrived in the mail offering a free book if I would renew. One
of the books offered looked interesting, so I sent email to the ARRL
asking if the offer could be made retroactive for those that actually
pay on time. No answer, yet. I wonder what would happen if I let the
membership lapse... perhaps an offer of two or more books? Grrrrr.....

Apparently, you must have attended the recent CES show, where
technology is sold by highly entertaining, minimally boring,
professional models.
<http://www.lvmodels.com>
<http://www.emmegirls.com/Trade_Show_Models.html>
<http://eventmodelgroup.com>
Compared to those, magic antennas are not even a close second.

There were a few magazines some years ago that I would let the
subscription lapse purposely. They always had a deal for new subscribers
or those who come back. Like half off the subscription price.

Good plan. I just received an email from ARRL member services asking
which book I might want. Of course, I picked one of the antenna
books.

Thanks. However, it wasn't a difficult decision. The options were:

- More Wire Antenna Classics Vol 2
- HF Digital Handbook
- Emergency Communications Handbook
- ARRL Repeater Directory
- Extra Q&A
- General Q&A

The difficult part will be to find a slot in the bookshelf. It's
crammed full of books with no space left for more.

Another mistake was to renew for 2 years, instead of one year. I
might have been able to get one book per year that way. Oh well.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to

477. Robot Antenna Problem

Newsgroup: rec.radio.amateur.antenna
Date: 2012-03-01 07:45:07 UTC
From: wmaier@nmt.edu
Message-ID: <8rWdnUapzuuetNLSnZ2dnUVZ_oSdnZ2d@nmt.edu>
Source record: 2744
Cross-posted to: alt.engineering.electrical,rec.radio.amateur.antenna,sci.engr.electrical

I am working on a project for school in which my group must design a robot that can remotely locate a beacon emitting a 433 Mhz signal. We are using array of two dipoles and phase monopulse comparison to make multiple angle bearings of the beacon, to which we will later apply some processing to provide a location of the beacon. Our robot will travel a straight path and we will know which side of the path the beacon is on.

We are using a mesh screen behind the antennas to direct their radiation path toward the beacon. We were wondering whether we should position both the screens parallel to the path we are traveling, or have the screens facing 45 degrees outward in order to get more directionality on the signal?

Here are some images of the two proposed designs. The black circles are the antennas, and the green lines are the mesh screens. Both images are top view:

The first design: http://i.imgur.com/79r4T.png
The second design: http://i.imgur.com/2oH5H.png

Thanks in advance for any help. Advice is greatly appreciated.

I have used XMLOG (shareware) for some time on XP and on Windows 7. It
has many many advantages and works with many rigs to automatically
enter time, frequency, and mode.

Further it has a good interface to LOTW.

For further information see www.xmlog.com.

Hi
Thanks for the reply.

My rigs are older and dont support interface hook up. Iam looking for a logging software that doesn't need hook up to the rigs.

Other than pad and paper, slate and chissel

Something independant and not reguired to hook up to the rig. I know there are a couple of old dos programs, not looking for that.

Thanks

73s

The second 45ï¿½ thing does not make sense to me.
You increase the capture range but decrease directivity.
Will the antennas rotate?

w.

484. Reliable RF Amplifier for Robot Antenna Problem

Cross-posted to: alt.engineering.electrical,rec.radio.amateur.antenna,sci.engr.electrical

Hi, it's me again. Does anyone know of a good reliable RF amplifier for the 433 MHz range? We need a gain of roughly 20 dB. We want to use it to amplify our received signal from the beacon. Thanks in advance for any help.

PS We realized the thing about rotating the mesh was not an issue. Thanks for the replies to that Paul and Helmut.

depends where you are situated,
look for something like that
http://tinyurl.com/7bmqw6q
broadband amplifiers, they are cheap and you do the filtering
by making a selective antenna.

Narrowband amplifiers are a little more expensive
http://www.minikits.com.au/eme173.htm

At http://www.dxlabsuite.com/ you will find a suite of programs which
includes DXKeeper.

It will interface with several sources of info such as the QRZ callbook
as well as eQSL and LotW and keeps track of numerous awards.

You can install as many or as few of the applications as you find useful
and they integrate with each other.

If you do any PSK or RTTY, WinWarbler is especially nice. It is also handy
in SSB mode since it is integrated with DXKeeper.

There are too many features to talk about here; see the web site for details.

FYI if you do not have rig or rotator control from your computer, those
things are just ignored.

Cheapest solution would be a television UHF pre amplifier.
The goal being the one with the lowest noise factor and the most gain -
while filtering out anything that would cause overload.

Without a physical address - where I could see what else is in the
neighborhood - there is no way for sure to answer your question.
Anything from Police stations to ambulances to fire stations to GMRS and
Amateur repeaters might create harmonics which could get into your
amplifier and cause overload.

Here is a cheap solution - http://tinyurl.com/7nj9yy6

Anyone remember the 3or4 band antenna, omni that needed to be right on the ground. I think it had 3 traps in it. Might have been for 10, 15 and maybe 40 or 20 meters.

It might have been a crushcraft or alpha. has to be about 30 or 40 year old antenna.

Anyone remember that old antenna? What was its manufacture? Model ?

thanks if anyone can remember.

492. What's the most accurate elevation tool on the net (freebie)

Newsgroup: rec.radio.amateur.antenna

What elevation tool do you use and how does it compare in accuracy?

I'm trying to do some antenna siting calculations ... and ... for
that ... I need elevation information.

However ... given any set of coordinates ... e.g., Mt Hamilton,
California at coordinates 37.337408,-121.644073 ... I find the following
elevation tools all give DIFFERENT elevations (some are off by more than
a hundred feet!)

1. Google Map API yields 1217.061889648438 meters (3992.985 feet)
http://maps.googleapis.com/maps/api/elevation/json?
locations=37.337408,-121.644073&sensor=false

2. Geoplaner yields 1217.1 meters (3993 feet)
http://www.geoplaner.com

2. Daftlogic yields 1230.988 meters (4038.676 feet)
http://www.daftlogic.com/sandbox-google-maps-find-altitude.htm

4. Earthtools yields 1210 meters (3969.8 feet)
http://www.earthtools.org

5. Heywhatsthat (SRTM db) yields 1213 meters (3980 feet)
http://www.heywhatsthat.com/profiler-0904.html

Q: Which elevation tool do you use ... & what's the accuracy?

Unless you are dealing with a surveyed peak, I would assume all the
elevation data is derived from USGS NEDs (national elevation dataset).
For the most part, they are only 1/3 arc second. I'm speculating that
some of these programs are reporting data from the NEDs as if they are
section of flat areas on the 1/3 arc second grid, while others are
interpreting the elevation using a weighting scheme.
> http://seamless.usgs.gov/

Have you considered running SPLAT! ? It uses 1/3 arc second data. It can
predict line of sight. Generally I find I do better than the SPLAT!
prediction, so if SPLAT! says no, the answer is maybe, but if SPLAT!
says yes, you have line of sight. The program has hooks for predicting
signal strength, models knife edge diffraction, etc.
> http://www.qsl.net/kd2bd/splat.html

Similar software is
> http://www.cplus.org/rmw/english1.html

For pure line of sight, there is GRASS. However GRASS has a very steep
learning curve.
> http://grass.osgeo.org/

What takes maybe 5 minutes on SPAT can take 2 days on GRASS. I don't
know if the results are that much better.

For the bay area, I suspect SPLAT! is fine. I think it's shortcomings
are in areas where there is really rugged terrain that probably isn't
modeled well.

Youre asking wrong questions.
First define a surface with height ZERO as a reference.
There are about 100 different definitions alone for that.
Distance from Earth center, median sea level at Novosibirsk,
or a San Francisco? Water isn't level, it follows gravitation.
And so on.

I'd use the info from another licensee's application, (on the same
tower). With the FCC you also must specify which survey you are using.
All towers over 200'(AIR) have their own entry in a tower database.

Those of you who are using apartment antenna I would love to know of your experience.

Now that satellite dishes are allowed on most apartments, is there a trend to use an MFJ loop antenna?

What are the real results with QRMing satellite dishes?

RFI in apartmements in general?

I am sure that putting a loop where the satellite dishes go would work great.

What power levels are people using in apartments.

I don't think I would want a loop inside due to high voltages.

Look forward to hearing from you all.

73,

Alan

I like full wave horizontal loops for the low noise receiving, a hiqh Q
transmit antenna on the patio is kind of cool; another type of barbecue.
I'd stick to CW/digimodes and under 100 Watts.

Thanks for the reply

This antenna is about 22 ft long, no gnd planes, I think it has three traps.

The base has the simple regular 2 ubolt connection to the pipe and the 52ohm coax hook up.

This antenna must be 30 years old or more. I have seen them at many a hamfest , was popular around here way back when.

My wondering is the lengths between each trap, it is telescopic aluminum and it is in pieces. Needs all new hose clamps for each tapered slit connection.

I have seen it before online but do you think I can find it now? I thought it was crushcraft or delta antennas. I will find it and post it.. Jeesh, just cant think of it.

Thanks
73s

A good tuner helps.

What about getting your appt on the top floor, then you can squeeze
something up top a dipole or two.

you know there are a lot of computer programs that allow you the use of ham
bands online. That is an option.

Any trees around you could rap a wire around? Any grounded towers already on
the roof you can shunt feed?

Some nice omni albanders out there very expensive, just get them high as
possible. Or go mobile, get one of those vehicles with huge antennas on and
drive to the mountain top and do your transmitting there. Lots of
possibilities.

SPLAT! isn't a photoshop hack, but you can use gimp (or I suppose photoshop) to hack with the png files it creates. I take the png files and chop them up so they are acceptable to google earth, then make an overlay out of them. Splat can do it, but unless things have changed, it makes a kml file that can be too large for GE to accept. GE wants tiled imagery. I haven't run it in maybe 18 months, so I can't really say much without setting it up again.

I saw a GPS mentioned. I never found GPS elevation to be too accurate. I have a barometer in my GPS. I never used it, so I can't vouch for it's accuracy. But you can enter in the pressure from the airport, or calibrate it to a known reference (known altitude for a position).

One idea would be to check the USGS monuments and find the closest reference.
> http://www.ngs.noaa.gov/cgi-bin/datasheet.prl

Note that sometimes these markers are on private property. Other times they are in the middle of the street! it pays to look at the reference on google earth before trying to use it. My Garmin gps60cs was good to 4ft, basically one lsb.

You could get a nearby reference, call the barometer, then quickly move to your spot before the pressure changes. Or you might get lucky and

find there is a marker there already.

Topo maps have lines of constant altitude, usually on 20ft contours. You could interpolate from the map.

If you really need accurate data, just pay for a survey. I would guess something that simple is under a grand. I've paid for land surveys and they are a few grand, but the altitude at one point is pretty simple. Potentially the civil engineering firm might have topo data on file that is not available to the general public. For instance, I paid for a satellite topo to be done on some property. The civil engineering firm has it on file and I'm sure it gets peeked at by other people.

Yeah, I read further though. It's one of those things where infinite
bandwidth requires infinite power, And almost infinite power pretty quickly.

This is a relative of the phase shift idea, where we can make smaller
and smaller shifts until we have amazing channel carrying capacity.

Too bad it doesn't work in the real world. Zero Point energy is more likely.

However, in the digital world, they think that Moore's law applies to
bandwidth, so there will be grant money to chase this wild goose.

If in the US, I would assume that the LAT/LONG uses either WGS84,
NAD27, or NAD83 datums. That reduces the number of available options.

Unfortunately, the USGS is still hanging onto NAD27, while most
mapping programs and displays are on WGS84.
<http://www.maptools.com/UsingUTM/mapdatum.html>
In the People's Republic of Santa Cruz, the error is about 20 meters
east-west, and about 1 meter north-south. I forgot which way. The
problem becomes really bad when trying to locate a mountain top.
20-200 meters of horizontal error can easily move a position from the
peak, to somewhere on the slope, resulting in large altitude errors.

SRTM and SRTM2 are another oddity. They were created from the space
shuttle, using a radar altimeter. Depending on the whether it's
looking at buildings or trees, there's no really good way to determine
of the indicated altitude is the top of a 100ft redwood tree, the top
of a 10 meter high building, or at ground level.

So, my list of rhetorical questions are:
1. What is the OP trying to accomplish? If for an FCC license HAAT
calculation, almost any reasonable guess will suffice.
<http://transition.fcc.gov/mb/audio/bickel/haat_calculator.html>
If for doing Radio-Mobile coverage contours, you'll need to use the
built in mapping tool to find the peak or exact location on the
mountain top. The choice of application depends on what one is
attempting to accomplish.
2. What level of accuracy is really required? The original position
of 37.337408N -121.644073W is specified to 1 millionth of a degree, or
about 0.09 meters.
<http://www.csgnetwork.com/degreelenllavcalc.html>
It would be interesting to know where this highly accurate number came
from. Better GPS receivers, without DGPS, can do 3 meters accuracy.
3. What datum are you using? I suggest WGS84. If the lookup tool

offers a choice of datums, pick one and stay with it.
4. Are you interested in ground level, building rooftop level, or
tree top level?

It seems you make the mistake of equating a "channel" in terms of
communication theory to a slice of bandwidth on RF. Those are
clearly not the same thing.

One can use the same RF bandwidth slice as a channel multiple times,
and thus transfer many times the amount of information such a communication
channel can theoretically carry.

Examples:

- horizontal and vertical polarisation of EM waves

- beam antennas beaming in different directions

- pairs of sending/receiving antennas that are shielded from eachother
e.g. by the curvature of the earth

Of course, the Shannon theory considers all those different instances a
different channel, each of which can carry a certain amount of information.

But as the user/licensee of a slice of spectrum, it is tempting to call
that slice of spectrum a channel and welcome any way of transferring more
information through it that was thought possible before.

And this seems to be what is going on here.

Of course, practical limitations on separation will make it impossible
to realize a large gain from this, let alone "an infinite number". But

that is just the journalists ignorance part of it.

I had a nice cw qso with a fellow in an apartment using a 9:1 unun made by balundesigns.com to a straight wire off his apartment balcony to a tree. Such a wire could be made very small and almost invisible, if that is a possiblity. Also, easy enough to homebrew your own 9:1 balun for such, if you are inclined.

If you could feed with parallel line, an end-fed zepp might work well, but would require an end support, such as a tree, and the parallel is more visible.

If the second support is not practical, many have used coil loaded verticals off a patio. This could be done with a collapsing fiber glass pole for removal when not in use.

Both schemes would require a tuner.

Yep. However, standing under the tower, in order to take advantage of this level of accuracy is often impractical. Climbing barbed wire topped chain link fences is not my idea of fun. I ran into the problem when I was throwing together a map of the local cell sites: <http://802.11junk.com/cellular/> (from about 2002).
I had a suitable GPS, but I couldn't get anywhere near some of the towers in order to get an accurate position. I had to record a GPS location nearby, measure or estimate the distance and direction to the tower, and then do the math.

I forgot to mumble something about HARN and NAVD88, if the best possible vertical accuracy is required:
<http://www.ngs.noaa.gov/faq.shtml>

Also, all the major mount tops have benchmarks pounded into the ground somewhere. If you can find the benchmark, you have the location, and sometimes the altitude. For example, for Mt Hamilton:
<http://www.waymarking.com/waymarks/WMQ1J_Mt_Hamilton_1960_ECC>
The problem is that mountains tend to move every time there's an earthquake. Even without earthquakes, the distance between Mt Hamilton and the Farallan Islands moves about 5 cm per year across the San Andreas fault.

I think this might help if you're trying to locate a tower on Mt Hamilton:
<http://www.ucolick.org/~sla/mtham/gpos.html>
"The vertical positions are not as well known and may
be off by 10 meters. "
Well, maybe not...

My objective was to determine my full Maidenhead before there were web
applications to find it.

I just took my portable, WAAS enabled, aviation GPS to the back yard and
let it average for a couple of minutes.

Since then I discovered why I kept getting different results pre-GPS (long
boring story about map accuracies); turns out the dividing line runs
down the sidewalk across the street.

Chuckle.

We're close to that problem at the local club station (K6BJ):
<http://802.11junk.com/jeffl/pics/drivel/slides/grid-cm8x.html>
I had to post this map because operators were constantly calculating
the wrong grid square.

Nearby, is the local intersection of the lat-long lines.
<http://confluence.org>
<http://confluence.org/confluence.php?lat=37&lon=-122>
Notice the wide variations in photos by people thinking they've found
the correct location. The problem is that the real intersection is
located on a poison oak infested steep hillside. We posted a DGPS
located marker, but people keep stealing it.

As it turns out, my house is in the very SW corner of DM14fco7, with the
front in DM14fco7ae and the back in DM14fco7be.

<mandatory antenna content>

If you go to http://no.nonsense.ee/qthmap/ and enter DM14fco7be the
white dot in the middle of the back yard is the box covering an SGC
autotuner for the 33 foot vertical.

A screwdriver antenna may work better than the Hi-Q loop. I'd check at
eham.com reviews.

The neighbors and are discussing setting up a neighborhood mesh network and we need to ascertain, beforehand, where to place masts and which direction to point them in our mountainous neighborhood (Skyline & Summit area).

> If for an FCC license HAAT calculation, almost any reasonable guess will suffice.

For us, probably any reasonable answer would suffice - but why not pick the most accurate for starters is what we're thinking.

> What level of accuracy is really required?
> The original position of 37.337408N -121.644073W is specified
> to 1 millionth of a degree, or about 0.09 meters.

A few feet would probably work just fine for the neighborhood. We each have acres of land, but the terrain is so rough that only a few spots for antennas would be useful. That's why we want to choose them ahead of time.

> It would be interesting to know where this highly accurate
> number came from.

We didn't want to put our actual location on the net, so, we picked an arbitrary set of numbers from one of the elevation calculators just as an example. But we're in the roughly 37,-122 range.

> What datum are you using? I suggest WGS84.

WGS84.

We have some numbers in NAD83 from the various WISP providers but they drive us crazy since we have to imperfectly convert them to WGS84 to keep our numbers consistent.

> Are you interested in ground level, building rooftop level,
> or tree top level?

All three because we want to site a dozen or more antennas which need to have clear line of sight over rooftops and trees by at least the first Fresnel zone.

Interesting quotes from that helpful reference (with my comments in parenthesis).

"In the Continental United States the difference between WGS 84 and NAD 27 can be as much as 200 meters." (I wonder how they handle the constant creep which occurs out here near the San Andreas fault line).

"Every map that shows a geographic coordinate system such as UTM or Latitude and Longitude with any precision will also list the datum used on the map." (I'd change "will" to 'should' based on my experience the past two weeks on the web)

"The Global Positioning System uses an earth centered datum called the World Geodetic System 1984 or WGS 84." (That's what I prefer.)

"For all practical purposes there is no difference between WGS 84 and NAD 83." (Good to know.)

"On a USGS topographic map ... The datum will always be NAD 27... A dashed cross in the SW and NE corners of the map gives a visual indication of the difference between the two datums." (This is good to know.)

"If you are engaged in a mission that requires more [than several hundred meters] precision, then your datums should match." (Since we're siting antennas on private hilly land, we probably want two or three meters accuracy in position and a half-meter to a meter in elevation accuracy so our datums must match.)

What I mean by that is that it's a right-slip fault, and it moves by centimeters to inches each year (sometimes in feet to yards, both in elevation and in position) ... but ... how do they know if the west side moved north or if the east side moved south?

I wonder what they use for their frame of reference since it depends on which side of the fault you're on if you want to say the west moved north or that the east moved south.

Ok. Go thee unto:
<http://www.cplus.org/rmw/english1.html>
Follow the destructions at:
<http://www.cplus.org/rmw/download/download.php?S=1>
For maps, download the SRTM3 maps for your area from:
<http://rmw.recordist.com>
Do not bother with DEM, SRTM1, or other maps. Do NOT unzip the maps.
My directory shows about 600MBytes of SRTM3 data for everything for
the SF Bay and Monterey Bay areas. You can set Radio-Mobile to
automatically download a map if needed, but it's easier to just
download the maps ahead of time.

Follow a simple example such as:
<http://www.cplus.org/rmw/afirst.html>
to get started. There are also numerous tutorials on the web.
Note that the program uses the concept of "networks" which will be key
to modeling a mesh. Locate your nodes, use realistic values, and
build a model. This part is a PITA and requires considerable time and
effort. Draw the (optical) coverage areas for each node, and the line
of sight:
<http://joelgranados.wordpress.com/2011/11/05/wireless-link-calculations-radio-mobile/>

You're going to have a big problem in the Santa Cruz Mountains call
trees. These are cellulose and water obstructions that may or may not
appear at the correct altitude on the elevation profiles. 2.4GHz will
NOT penetrate foliage, especially when wet. You'll need to manually
adjust your path profiles for the tree line. If the trees are inside
the Fresnel zone, you'll have losses.

If you have problems, ask here, or preferably the Yahoo Radio-Mobile
group at:
<http://groups.yahoo.com/group/Radio_Mobile_Deluxe/>

I have a really bad attitude about mesh networks. Bug me if you want
to hear the full rant. For a sample, see the dismal performance of an
early mesh network (MIT Roofnet -> Meraki).
<http://pdos.csail.mit.edu/roofnet/doku.php?id=interesting>
"Surprisingly, the performance over a two hop route is
less than 1/2 that of one hop routes, implying routes
tend to interfere with themselves."
Also:
<http://sha.ddih.org/2011/11/26/why-wireless-mesh-networks-wont-save-us-from-censorship/>
covers the main problems. Do you really want a phone call at 2AM from
a neighbor asking if the network is down?

Some years ago, I got in a major pissing contest with a high ranking Dept of
the Army civillian because he wanted a study of zero bandwidth transmission.
His theory....with zero bandwidth there would be no noise, and thus an
infinite signal to noise ratio. They are still out there......

This is an interesting antenna HAAT (Height Above Average Terrain)
program ... but I'm not quite sure what use it is because it gives a 360
degree average height ... but most 2.4Ghz antennas I'm dealing with are
directional.

You enter the latitude, longitude, & height of the antenna, and then it
tells you, for example, for 360 degrees, the average antenna height above
ground for 2 to 10 miles along each radial, the result of which can go
negative.

The output is a text file. It's interesting, but, without graphics, I'm
not sure how to use the results properly when just going point to point.

We simply must repeal the laws of physics - they just get in the way.

Upon further looks at their document, it looks like they are putting
that continual twist on the signal by cutting the parabolic dish, then
moving one side of the cut a little closer. Apparently that makes the
signal twist continuously.

Bloody hell, they should have saved that for April 1st.

I wrote that before you disclosed what you were trying to accomplish.
Had your intent to obtain accurate altitude readings been for the
purpose of applying for an FCC station license, you would have needed
the HAAT calculations to estimate coverage area. For building you
mesh network, you don't need HAAT calculations.
<http://en.wikipedia.org/wiki/HAAT>
The first paragraph should explain what HAAT means.

>The output is a text file. It's interesting, but, without graphics, I'm
>not sure how to use the results properly when just going point to point.

Hint: You can always take a table of number and create a graph or
graphic. Going the other direction is not so easy. Most propagation
and antenna design software generates an output table (text file),
from which a graphic is later generated.

I've used Radio Mobile and SPLAT!. I never got a warm and fuzzy with
Radio Mobile. Of course, it is a bit more complicated to use SPLAT!.

One obvious advantage to SPLAT! is it can analyze very large areas. Not
all that useful in the case of this wifi setup, but very useful in sigint.

Oops. I meant the SRTM1 maps.
<http://dds.cr.usgs.gov/srtm/version2_1/SRTM1/>

>I've used Radio Mobile and SPLAT!. I never got a warm and fuzzy with
>Radio Mobile. Of course, it is a bit more complicated to use SPLAT!.

I've used both. Radio-Mobile has a very steep learning curve.
Important functions are buried deep into obscure menus, useless trivia
is scattered all over the menus, there's no logical sequence of
operation, and many of the terms require expertise in cartography.
Debugging errors is tricky as important items, such as the performance
characteristics of the radios, are scattered over a half dozen menu
pages. I find myself constantly referring to my cheat sheet in order
to get anything done. However, I haven't found anything else that
even comes close to what it does.

>One obvious advantage to SPLAT! is it can analyze very large areas. Not
>all that useful in the case of this wifi setup, but very useful in sigint.

<http://www.qsl.net/kd2bd/splat.html>
Splat is somewhat easier to use, but as you note, is designed to
display repeater coverage. It's less useful for close in coverage, or
showing coverage details, as in mountainous or urban jungle terrain.

Both programs put considerable effort into implementing complex
terrain models. For 2.4 and 5.7Ghz, optical line of sight is close
enough.

Is that suppose to be some kind of thanks for doing your research?
In the future, if you need assistance, get it from someone else.

RM mostly runs under Wine:
<http://radiomobile.pe1mew.nl/?How_to:Wine>
The problems listed are not fatal as you can download the SRTM maps
manually, and can simply export the result as a Google Earth overlay
to obtain street map detail.

My recollection of Radio Mobile is you need to crank down the minimum
angle that it sweeps to get any accuracy. Like I said, I prefer SPLAT!
for the accuracy. Even so, it is only as good as the NED. However, if
SPLAT! says you can see it, then you can see it. I thought Radio Mobile
was simple to run, at least for one transmitter at a time. Far easier
than SPLAT, which requires compilation parameters to set the array size.
Radio Mobile, at least when I read it, was stuck at 3600x3600. If you
exceed that array, and note it uses a 1/3 arc second grid, the program
interpolates.

The grid is 10 meters on a size for 1/3 arc second. That means you can't
"see" more than 36km. Plenty for wifi, not so good for repeaters or even
photography.

I generally do two runs with SPLAT. First I check the altitude when the radio is to be located. If it doesn't match the topo map, I add the difference in altitude to the transmitter height. Then run it again.

I have a 90 mile path to analyze, so I guess I'll see what these programs can do lately. But if Radio Mobile is stuck at 3600 pixels, that is a show stopper.

If Alpha Male has linux, why even screw with Radio Mobile? Just run
SPLAT!. For a small array, the KML SPLAT generates should be fine for
Google Earth. My issue was the array was too big to feed GE directly.

GE has an "aperture" size that doesn't appear to be consistent between
PCs. GE expects the images to be tiled with no tile larger than the
aperture. On my PC, that is 3600x3600. That is probably why you could
load the Radio Mobile output to GE.

Incidentally, there are programs designed to take a PNG and tile it, but
I never got them to work. But it has been a while since I tried them.

True. 1 degree resolution at perhaps 20km is:
tan(1deg) * 20km = 350 meters
resolution. Not great resolution, but good enough for wide area
coverage. For wi-fi, the range is much less, so the "squares" shown
on the map will be correspondingly smaller.

Samples of wide coverage area RM calcs.
<http://802.11junk.com/jeffl/coverage/k6bj/>
We recently moved our tower and antenna, when the building that
previously supported them was demolished. So, I recalculated the
coverage. I believe I used 1 degree resolution.

I'm too lazy to check the numbers right now. Maybe tomorrow.
Meanwhile, this article claims that Splat is limited to 3600x3600
while Radio-Mobile is limited to 2000x2000. No clue at this time
who's correct.

>I have a 90 mile path to analyze, so I guess I'll see what these

A 90 mile PATH (line) is quite different from a 90 mile radius
coverage (area) radius.

Looks like the balloon trackers have the same problem with Radio
Mobile Deluxe.
<http://showcase.netins.net/web/wallio/RMD.html>
"The 2000x2000 software elevation matrix limits paths to
2000km for 1000m data (30-arc second), 200km for 100m
data (3-arc second) and 130km for 30m data (1-arc second)."

Now, go away so I can get some work done...

Hi Engineers,

I'm Starting a new FM Station Project in BENGHAZI - LIBYA which is 60km2 in area, i was advised to use a transmitting system of a 600w Transmitter attached to 4 double dipole antenna (http://www.labelitaly.com/website/akk2.html) as my tower specs are : tower angle 4 leg (leg size = 10 x 10), parameter at 96 m height = 2.5m x 2.5m. attached a picture of my tower.

i want to get an omni-directional coverage as my tower is located in the center of the city and I've been told that unless a panel antenna the tower will make a shadow or something like that to the broadcast signal.

i want to know if i'm really forced to use a panel antenna in my system, why i can't use a high power regular dipole antenna.

and please advice if the transmitter power i'm using will be enough to cover the 60km2 area.

hope to find help here.

Thanks in advance.

Why are looking at a flat panel directional antenna when you want a
omnidirectional antenna?

Nothing attached!

You might be able to use a simple sleeve dipole, ground plane, or suchlike at the top of the mast if that's vacant and you can get an antenna that's happy to work as the lightning finial, but the antenna gain will be low to the intended service area; possibly less than 0 dBd, particularly in the case of a ground-plane antenna (upward-tilted VRP: radiation pattern in the vertical plane). For police communication at similar frequencies in the UK, four two-element yagis around a pole were used at the top of the structure, the pole actining as the finial. Usually, two such arrays were stacked vertically. The small radius of such an array gives a good omni HRP (radiation pattern in the horizontal plane).

An advantage to using a circular array of panels is that it can be positioned below the top of the structure (e.g. if the top is used for television) and you might achieve a minimum of 0 dBd if the handovers between adjacent panels are well controlled (or fortunate!). At many stations in the UK, a number of tiers of panels are used in order to provide gain and to facilitate a split upper/lower half-array system for resilience. You could try to get the antenna supplier to measure four panels on a stub tower of the same cross-section as your structure, but if you're only buying a one-off they might charge you a premium for perefoming the measurement. It would demonstrate unequivocally what the final system would achieve HRP-wise, although, depending on the height of the stub tower (or time-domain gating, etc.) you might still need to infer the VRP.

A service area of 60 km^2 would have a radius of 4.4 km if it were circular - is yours? The required ERP depends on the required minimum field strength at the limit of service. For simple spherical spreading, taking no account of antenna VRPs and reflections/multipath, E=(7/r)sqrt(ERP) ... which can be found in ITU texts and is easy to derive from first principles ... so if you were to use, for example, a minimum field strength of 5 mV/m (stereo, in a large city with lots of sources of interference, using low-gain receiving antennas) at r=4.4 km, then ERP=9.9W. If your service area isn't circular, say it extends out to 10 km in one direction, then to achieve 5 mV/m at 10 km would require ERP = 51.0 watts. A 600 watt transmitter into an antenna system with a net gain of, say -3 dBd (accounting for VRP, HRP ripples, and combiner/feeder/power-splitter loss), would provide an ERP of 300 watts so, in the latter case, a margin of 7.7 dB. This would provide some resilience to multipath fading (although P-P=0, no matter how large P is!). In other words, you probably wouldn't need a higher-powered transmitter in this case - but it does depend on the shape of the service area, and on your definition of 'service'.

Hope this helps.

Chris

Another reason for using panel elements is to facilitate horizontal polarisation, which was popular in the UK (but perhaps for a questionable reason) - nowadays, most stations use mixed or vertical polarisation. When the majority of the listener-base is located in vehicles, VP is a better choice principally because of the typical receiving antenna.

Chris

Yes. I'm just mentioning cranking down the angle to save someone a few meaningless runs. It didn't occur to me to do the math as you suggested, but it makes perfect sense.

I was running the beta version of splat-hd. I could do 6 degree x 6 degrees at 1/3 arc second. Each degree is 3600x3600, so I could do 21600x21600. If you want to do "mountain-topping", you need that kind of span.

Looking at the overlays I generated, I had to hack the output into 12 to 20 blocks, 3600x3600 at a time, to make it google earth compatible. Hopefully the new version does this automatically.

I believe this was the program I was trying to get to work to do the cookie cutting. Looking at the bug report, it still looks like it has issues.
> http://www.maptiler.org/

I got really good with GIMP to do the cookie cutting. Still a PITA.

First sorry that i forgot to attach the picture of my tower, it's
attached now in this RAR File :
http://www.mediafire.com/?cse8yiyn5d4jtd9 .

I'm Forced to use panel antenna cause the person i'm buying the antenna
from told me that my tower specs can handle nothing but a panel antenna
to get the desired coverage cause if i use another system of antenna the
tower will make a shadow to the transmitted signal and that's an
information i don't trust, the panel antennas are so expensive and heavy
for shipping so i'm asking for a replacement for those antenna that will
work with my tower and gets me an omni-directional coverage.

can you verify this information?

Unfortunately i'm renting a place in the tower which is 80 m high and
the parameters of the tower at 96 m high is 2.5m x 2.5m so it's not
gonna be small in radius for the antenna system.

Ok let us Stick to the 600w transmitter, i'm not an expert in waves calculations glad to have such help from you, you can see exactly the picture of the tower and the position of it in this RAR FILE http://www.mediafire.com/?cse8yiyn5d4jtd9 , attached also a placemark from google earth for the tower location in the city, Benghazi's surface has a lot of area exposed to the sea at the north west, and there are hills at the south east, i only want to cover the residental area in between which is a cicule of 15 km of radius, getting a wrong pattern antenna will waste most of my signal into the sea, please recommend me an antenna system which works with the 600w transmitter and the tower specs i mentioned (tower angle 4 leg (leg size = 10 x 10), parameter at 96 m height = 2.5m x 2.5m) and also for the geographical charecteristics of the city and also want to get use of the gain of the antenna i will get to strength the signal (my tower is the one at the left)

thanks in advance

I don't have software to read .rar files - perhaps you could provide links to .jpg photos that can be read by Windows without needing to download a reader program.

If the aperture you're renting is at 80 m on the 96 m tower then, clearly, you don't have access to the top so you can't use a simple omni-directional antenna. If you mount a half-wave dipole any reasonable distance off the

face of a tower with side dimension similar to the wavelength then the resulting HRP will be directional (viz the 'shadow' principle you mentioned, and reflection off it). You may be able to use one or more such directional patterns if your service area isn't uniform around the antenna but if your aim is consistent coverage at all angles around the structure then you will need to mount an antenna off each face, and that's the purpose for which panel antennas have been designed - to achieve controlled hand-over from one panel to the next so ripples in the HRP are minimised. It isn't trivial to predict the radiation patterns of an antenna next to a metal structure and many manufacturers offer sytlised patterns based on averaged measurements. One manufacturer has already been named by amdx and there are many others you can Google (e.g. RFS, Alan Dick, R&S, Harris, etc.).

However, since your service area covers a limited arc, bounded by sea and hills, it sounds like you don't want an omni-directional HRP at all - more a precisely-tailored directional pattern. It would probably take range measurements using a stub tower to get that right - but it all depends on how precise you need to be (e.g. on the definition of your coverage criterion).

You will need to do some research into this (or pay someone to do it for you) if you don't trust the advice you're being given by a supplier. There may also be regulatory issues to contend with. It goes without saying that you shouldn't base your purchase on anything written in this or any other newsgroup!

Chris

Katherein Scala antennas makes some very nice low power Yagi-Uda transmit
antennas.

Come on hams

You know the antenna I am talking about. I seen its specs online about 10 years ago. It is a single omni aluminum antenna with three traps in it. About 19 or 21 foot long. Made for ground use, no ground planes or radials, and old style. This is an older style antenna. Regular coax hook up. I need to remember the name of this antenna so I can make sure its lenghth and specs are correct. Gotta be an old ham out there that remembers these old style omni antenna.
Thanks

There were many versions of trapped verticals sold in the last 30
years. Without pictures of the base or traps, hope of identification is
fairly slim.
Sounds like the typical Cushcraft or Hustler. Or at least those were
the most popular versions.
Also, ground mounted verticals will still need radials if the antenna
is to live up to it's expectations. And there is nothing to stop one
from using one elevated, if one uses resonant radials for each band to
be used.
Look at the tubing and see if it has any marks on it from it's previous
assembly. Often, the clamping will leave marks on the tubing, and one
that was used for a long time will usually show discoloration between
the tubing exposed to the air, and the part that was covered due to
the overlap.

My GAP Titan DX requires no radials; it is a center fed, asymmetric
vertical dipole.

The OP should try using Bing or Yahoo. Here's the Yahoo Ham Antenna group:
http://groups.yahoo.com/group/ham-antennas/?yguid=353505133

Well, ground mounted monopoles in his case..
Being a "complete" antenna, it's true that the center fed vertical does
not require radials for proper operation, but you would still likely
show lower ground losses if it were over radials.
For instance, broadcast stations that use 1/2 wave radiators still
use a set of radials under the antenna. Usually 1/2 wave radials, when
used with a 1/2 wave radiator.
You will still see some ground loss with the ground mounted 1/2 waves
over poor ground, but being as the max current point is 1/4 up from the
ground, it's not near as severe as the ground mounted 1/4 wave where
maximum current is at the base.

I don't think a ground screen is needed if you are > 1/2 wave.

If you elevate a short vertical you only need a few "ground" radials
(think CB groundplane antenna), btw. My whole transmit antenna system
floats on my roof. The only "ground" is the panel where the RF goes
through the wall. I receive on a balanced 30m horizontal loop, also
floating except for the point of entry. I have an automatic tuner at the
feedpoint under the eave by my kitchen window. (FWIW) I have lived here
14 years and have never seen lightning at the shack.

It's not required to provide the lower half of the antenna, but
they will still reduce ground losses if the antenna is ground mounted.

The number of elevated radials needed to equal certain number on
the ground will depend on the wavelength above ground.
IE: to equal 120 1/4 WL radials on the ground, at 1/8 WL, you will need
appx 60 of them. At 1/4 WL, appx 8-10.. At 1/2 WL, 3-4..
And if the radiator is short, the radial system is a bit more
critical than with a full size 1/4 wave radiator.

I bet their halfwave is sitting on a bed of 1/2 WL radials.
Most 1/2 wave BC antennas tend to use 1/2 wave radials I'm fairly sure.
Part of this is due to FCC requirements for stability in performance,
etc..
A 1/2 WL radiator on the ground is not immune to ground losses.
It just suffers less than the 1/4 WL.
And a 1/2 wave elevated, really should be decoupled from the feed line
for best performance. Of course, it's not required, but they will
perform better if you use decoupling. Less skewing of the pattern
off the horizon, from feed line currents.

Found it

Actually, I found some very old schematics , the paper is yellowish tea
like. Japanese I think . Hidaka.

http://www.hidaka.com/e-a_multi-v.html#VS-41W

I am pretty sure the one I have now is the VS-80KR.

I am going to clean it up and try it out. Don't know what will happen when I
put it on a 50 ft tower in these windy days. Will have to calculate the
length of gnd planes. I suspect they will be too long.

Any recommendations?

Thanks

Not really, as the antenna in the picture seems to use
loaded/trapped radials. So you will need their assembly
specs if you have those and plan to use them.
Or maybe assemble them and try to tune them.
If elevated, any full size wire radials will need to be resonant.
If ground mounted, there is no need to tune radials laying on or in
the ground.

I don't have the ground planes for this antenna, just the vertical main mast.

Used on the ground would be difficult because I am sandwiched between houses all around me.

I wonder would the mismatch be so significant that the efficientcy of the antenna be almost completely lost? If used with a good tuner would the radiation resistence of the antenna become totally innefficient if I were to completely ground it out through the tower? Nice idea having a omni all hf band antenna. I run barefoot anyway.

I think I will try it out anyway, I have one of those MFJ old manual tuners and am sure it would match the feedline coax with the antenna to the load. Just curious how efficient the antenna would radiate. Being 50 foot above the ground, approx 500 ft above sea level anyway. I think the deciding factor is that there is nothing on top of the tower now anyway.

Thanks

WGS84 is a geographic coordinate system: it's referenced to the Prime Meridian and the Equator, not to any ground landmarks locally.

the digital elevation data is "accurate as of the date of collection". If a fault moves or someone engages in a big earthmoving operation, then the data set won't reflect reality.

As to the practical problem of determining plate movement? Easy if you have GPS, because GPS is referenced to WGS84, and WGS84 is referenced to a specific geoid, anchored at the equator and the prime meridian. In turn, one can use celestial landmarks to calibrate it.

Hey y'all - I'm new to this web site. I have an old Cushcraft R7 vertical antenna that's going up one more time. It was new in '92 and got took down by a tree in a tornado storm in '96 in Zion, IL. I fixed it up and it spent the next five years above my mom's garage in Rocky River, OH. I took it down and it's been mothballed since. It's going up again because I cannot decide between other antennas. It is most definitely a compromise, but I do not contest or compete, and the ground here on the gulf coast is pretty salty, so I'm giving her another try.

This is so much fussing. I really need the two meter yagi up and running.

I wish y'all every one the best.

It's one of the best antennas I ever used in over 50 years
of hamming. I've had wires, towers and beams, but the
R7 was great! I never considered it a compromise. If you
do have problems with it, just google it and you can get
all the information you need to fix it quickly and easily. You
shouldn't have problems though. I set mine up according to
the manual and it worked perfectly for a number of years until
I moved into a senior's lodge and coudn't take it with me.

Thanks! The R7 worked well for me and later for my mom. I had it up on a ten-foot mast in Zion, IL. A nice op up in Kenosha, WI about twelve or thirteen radio miles to the north also had an R7 up on his garage and we could just about pin each other's S-meters on 40 with 100 watts. The tornado storm caused a big tree to fall on one of the 3/16" Dacron guy ropes and the antenna bowed severely, but I was able to fix it (the insurance paid for a new one!).

At some time during one of several Navy moves the counterpoise spokes and the x-hat rods were lost. I ordered replacements from MFJ and it took them five months to get the parts to me. A local ham has advised me to wipe the aluminum a few times per year with WD-40 against the salty air here on the Gulf. One concern is the longevity of the fiberglass base insulator in the South Texas sun, and I am contemplating coating it with roof tar. Any suggestions along this line are most welcome.

Dunno.. I think I would use something else.. That roof tar can
really get to be a mess if you have to work on anything.
And it possibly could effect the fiberglass being an oil type
product. Don't know how it's built, but maybe heat shrink tubing,
or some coating that wouldn't be so messy. IE: I'd much rather use
black color weatherstrip adhesive to cover it, than roof tar.
It will dry to be like rubber, and could be peeled off if needed.

No telling how it will tune. If you use no radials, the whole
structure will be acting as the antenna. Radiator, and tower.
Results could be all over the map depending on the band. It would
be better to have at least one resonant elevated radial per band to be
used.

Yes I agree. A big tube of heat shrink custom cut sounds much better.

This was an excellent antenna for me, and I set it up for my mom prior to a Navy transfer after my dad passed away. She had very good luck with it. I'm glad to finally have all the parts again. The R7 was really good, especially on 30 meters for me. I will forget the roof tar! I'm sure it would work, but what a mess! I need to open the box that contains the feed circuitry and verify everything is nominal, and check it all out. This should be a good location for the R7. Thank y'all for the excellent observations. Ric

Have you seen the product called "Rescue Tape"
Resisting salt water and UV rays are a couple of it's
characteristics. I bought some at a hamfest, but I saw it yesterday at
West Marine.
It doesn't leave any sticky residue when you remove it.
Here's the website.
http://www.rescuetape.com/
Mikek

I don't work for the company, but I did stay at a Holiday Inn.

Thanks for the information.
I think it is very top heavy, and up on a 50ft tower will just wait for a good wind to bring it down.

While I see no ground plane brackets with this, there is no way to put gnd planes at each section.

Haven't done nothing yet, maybe wont. Maybe will.

Thanks for the information.

I was looking at an engraving of an early ham shack. One thing about these old-time images that has always piqued my interest is the antenna- usually 4-5 parallel wires evenly spaced above the roof.

What type of antenna is it? End-fed or mid-feed making it a type of dipole? You don't see them any more, so they must not work too well, right?

Anyone have anything to offer?

David Quest;788733 Wrote:
> It's alive and well.....Spread the word

The problem is not if it is alive or dead, it is the quality of people involved with amateur radio today.

I see a couple of different types of people.
The leaders
The followers
The Sheep
The dumb asses with the walkie talkies, cell phones, voip - computer - that doesn't want to do Ham Radio - they want to do Cell Phone and Computer radio.

Then you have the old guys - who have done it all and doesn't want to help anyone - is too old to buy anything new, spends most of their time tuning up over other peoples QSO's and only talks on nets.

Then you have the old hams - the guys that were licensed as teen agers, realizes that the old hams are going to die or retire. That thinks that the world owes them something. Wants to be the section manager or regional manager of the ARRL. The low life scum that thinks that it is political.
Who gets the sheep to blindly follow them, gets the followers to follow them - with the promise that they will help them someday - maybe.
Assumes the role of leaders at their local clubs - but doesn't really do much of anything.
For the most part - you have a lot of clubs where the President makes all the rules and demands that everyone else just blindly follow them.
The followers thinks that belonging to a club will automatically make them ham radio operators - yet the President and the officers don't actually teach anything, doesn't actually Elmer anyone and their only goal is to use the club as a stepping stone - get the votes to become the section manager etc and then the people who helped get them to where they are at - are forgotten.

Just look at the officers of the ARRL and see where they came from, and their age, and the people who are lining up to take their jobs.

Then you have the Vultures.
You know who you are!
The ones that circles a mans house when he is dead or dying.
Looking to steal all of his / her ham radio equipment when they die.
Probably the main reason why there are so few hams who becomes Generals.

Once people gets their Technician Class License, finds out how much new radios cost, can't afford a used radio - even if it is available and just drops out after a couple of months or years - because there is no incentive to advance.

The clubs preaches public service and ECOM - but doesn't really do much of anything about it.
Most people cannot take traffic and are unwilling to even talk on the radio.
They are of no use to anyone in a emergency - unless the only traffic you want to pass is their call sign and No Traffic - because that is all that they have said on the local nets all of their ham radio careers.

I believe it is called a flat top antenna. I've seen them in old pictures of Navy ships, strung between masts and/or stacks. A bit of research seems to indicate they could either be center-fed as dipoles or end fed as inverted-L's. (If center-fed, I don't know why it wouldn't just be a fan dipole.)

My experience with Navy antennas is fairly extensive and I never saw one on any ship, so apparently they gave way to the fan-wire antenna. The fan wire, or just fan, is hung vertically or almost so, fed from the top, electrically less than a quarter-wave, and consists of multiple strands to aid in the broadbanding effects. All the fan wire antennas I ever saw were fed through a matching network to keep the SWR under 3:1 across the band of interest. The matching network box usually contained a Tee or Pi network.

Done. I hope it helps.

I spent a few years on pre-war Frigates and used flat-tops a lot. I never
did
any technical comparisons but we always managed to get our communications
through. I am a firm believer in the idea that any piece of metal that can
be
loaded will get a signal out, but it's kind of like firing an arrow into the
air
and not being sure where it will land. Usually if you could hear a signal
from
the area you wanted to send to, you could get through to them.
Likewise, if you can hear a ham reasonably well, chances are that
you will be able to work him.

Picked this up from an old newsgroup post.
.....
Flat-top arrays were used for low frequencies where the useful radiation
was from the vertical portion of the antenna. The simplest flat-top is a
T-antenna. They were used instead of an inverted L-antenna as the
radiation from the horizontal portion of the antenna was cancelled by the
symmetry of the two horizontal sections. In essence, the flat-top
portion of the antenna was a "capacity hat" in modern parlance. The more
the number of horizontal wires, the more capacitance, and the more the
antenna efficiency was increased (although it was still extremely small).
Better efficiency was obtained by arranging the horizontal wires in a
conical or cylindrical fashion as in a truly flat flat-top, the antenna
current tends to concentrate in the outer wires.

Probably the best information about these low frequency antennas can be
found in "Radio Antenna Engineering" by Edmund Laport. I believe a copy
is now posted online. To illustrate a flat-top design, I will post a
drawing to the alt.binaries.pictures.radio Usenet newsgroup. Since the
"alt" groups are not carried by news.eternal-september.org, I will have
to post using nntp.charter.net which frequently does not work.

73, Dr. Barry L. Ornitz wa4vzqNO
.....

Here's a link to a download of "Radio Antenna Engineering" by Edmund
Laport. It has been reported to have lots of info an low frequency antennas.

In the sixties we had offshore medium wave "pirate radio" ships, and
one of them had an antenna like that. I once tried to get details about
how this antenna was supposed to work, but never got a reply.

The ship initially transmitted in the high end of the band, and the
antenna looked like 5 wires spaced about a metre apart between the
two masts of the coaster, with a vertical wire in the middle connecting
to all 5 wires in parallel and leading down to a tuning unit in a small
housing on the deck. My theory is that it indeed was a vertical radiator
with a capacitive top hat. The height was only about 20 metres, so the
vertical was maybe 1/8 wavelength.

Later, the station went QSY to the lower end of the (medium wave) band,
and the antenna had to be changed. It must have been a big technical
challenge, to construct an antenna that small for a medium wave
transmitter at 556 kHz. What I have been able to find about it describes
the antenna (which still looked the same) as a vertical that ran to the
top hat, which now no longer was 5 parallel wires but a single wire that
ran zig-zag between the endpoints. So, 4 times forward and backward
between the ends (about 20 metres apart) and then to the middle and down
to the tuning unit.

How that did ever work reasonably is beyond me.

It does indeed, and it does discuss flat-top LF antennas in some
detail (they're basically capacitively-loaded verticals, as stated).

http://snulbug.mtview.ca.us/books/RadioAntennaEngineering/ will get
you to several download links.

That's four types, not a couple.. Although I suppose there is some
redundancy involved. IE: many dumbasses are sheep, many sheep are
followers, and most followers tend to follow the leader. :/

>
> Then you have the old guys - who have done it all and doesn't want to

Maybe they are tired. And they probably already own everything they
need, and thus have no need to buy more stuff. As far as the tuning
and netting, I would consider that a personal problem..

>
> Then you have the old hams - the guys that were licensed as teen agers,

I've been a radio buoy since I was a teen. So I guess I sort of fit
this category. And I do realize that everyone retires, and then dies,
sooner or later. This is another personal problem that all must deal
with sooner or later. Novice through Extra.. All are gonna be worm
food some day.. Death is not picky, and death took the 20 wpm
code test, so even CW ops don't get a pass on death. :|

Thinks the world owes me something? What would that be?
As far as I know, no one owes me anything, and as far as myself,

I owe very little.. :/

But, if the world owes me something like you say, I'll take an old Ford
GT-40. I'm not too picky about the color.

Want to be section manager or regional manager of the ARRL?
Are you kidding me? You couldn't pay me enough to involve myself
with such silliness..

> Who gets the sheep to blindly follow them, gets the followers to follow

I don't do clubs..

>
> Just look at the officers of the ARRL and see where they came from, and
> their age, and the people who are lining up to take their jobs.

Why would I waste my time? I could care less about the officers of
the ARRL, and I could care less where they came from.
And if someone wants their jobs, how long is this line?
Are they as long as the lines that form outside of shopping malls
when a new brand of sneaker comes out?

>
>
> Then you have the Vultures.

I've never seen a bird get a ham license... I guess they can
pass it now that they did away with the code tests.. :|

> You know who you are!

Yes, I know who I am. :/

> The ones that circles a mans house when he is dead or dying.
> Looking to steal all of his / her ham radio equipment when they die.

Radios, radios, and more radios!!!! Yee-haw!!!!

> Probably the main reason why there are so few hams who becomes
> Generals.

Maybe so. After all, why would one upgrade to a higher license,
if one has to constantly worry about some vulture flying over and
dropping a vulture turd or two on their heads... :|
They practice this you know.. It's kind of like learning to drop
fire fighting mud and chemicals on forest fires, except on a smaller
scale.

Life's a bitch, and then some people make the mistake of
marrying one.. :/
But realistically, it sounds like they need a better job, more
than they need a ham license.

I have loads of radios.. So many, I can't even keep track of
them all. Big radios, little radios, and many radios in between.
I think they secretly breed when I'm away, and spawn more little
radios and radioettes..

>
> The clubs preaches public service and ECOM - but doesn't really do much
> of anything about it.

I don't do clubs..

> Most people cannot take traffic and are unwilling to even talk on the
> radio.

Well, why don't you teach them then..
BTW, myself, I can handle traffic. I'm ex-MARS, where they actually
do run a bit of traffic from time to time..
But very few people rely on amateur radio to pass traffic these days.
So even though I can handle traffic, I rarely have the chance to
show off such advanced radio skillery. :/

> They are of no use to anyone in a emergency - unless the only traffic
> you want to pass is their call sign and No Traffic - because that is all
> that they have said on the local nets all of their ham radio careers.

I'm of total use in an emergency. I can do anything anyone might
want to do, and I can do it from any location on the planet.

But, I rarely do nets.. Too boring for my blood.

My idea of ham radio is sitting out in the middle of the woods,
sucking down a few cold ones, kicking back, and talking to all them

good ole buoys on the radio.

No one ever follows me. My woods are so secluded, no one would ever find me even if they tried.
I do see some vultures from time to time, but then again, I see a lot of birds out in the woods.

Worrying about nets, managers, clubs, and vultures is no way to go through amateur radio. Sounds pretty danged boring too..

I watched this and some of his other vidios a week or so back.

I have learned more from him than I got from any other books I have read..
Seems that all the other books were wrong. I had a First Class Phone
license almost 40 years ago and an Associate degree in Electronics
Engineering.

I need to ge back to school and see what has changed. Maybe he is using the
new math to calculate the SWR.
Must be government matn.

What were the references to "the three-field" and "the five field" or maybe
"the far field"? Did anybody make that out? (Started around the 1:45 mark.)

He does say "a lot of CB'ers" once, which identifies him, I think.

Looking at portable and easy to deploy method of putting up a 5/8 omni directional antenna for CB/10-11m trans/rec. Is hooking up an antenna wire to a helium balloon on the "top" end and connecting it to coax at the "bottom" a possible option? Obviously there are many environmental limitations with the concept, and it is a strictly single use application. But for camping or emergency back up use, the concept sounds at least plausible. Anyone have any technical reasons why this is not feasible? Better yet, anyone have any experience with anything similar?

If you include operation in the rain then the balloon needs to be attached to a low-voltage point on the antenna - certainly not the end of a dipole element because a wet string leading to a wet balloon would likely detune it. Some people I used to know used discones in this application, and the centre of the disc is a relatively low-voltage/low-impedance part of the antenna. The technique was used extensively in planning the UHF transmitter network for television broadcasting in the UK, before computer modelling and simulation was allowed to take over with remarkably little proof of its accuracy!

Chris

I would not use a 5/8 antenna, as this requires 1/4 lambda radials,
and has (virtually) no advantage over a half wave. A half wave wire
end-fed antenna design can be used without radials mostly.

If you use grease impregnated wire, or monofilament line to tie the
antenna to the balloon, it will not reduce efficiency, even under wet
conditions. Of course you could also use a plastic insulator. you may
know raising the antenna will enhance ground wave propagation, but
above a certain height will not improve ionospheric propagation.

Why not use a fiberglass mast?

610. Batterycharger ??

Newsgroup: rec.radio.amateur.antenna
Date: 2012-03-27 00:22:09 UTC
From: Tuuk <abraaaa@cadabraaaa.ca>
Message-ID: <JK7cr.43877$M%7.39334@newsfe10.iad>
Source record: 2577

Hi
Anyone familiar with the Energiser CHDC-CA Battery Charger? That just happens to be the model number of the one I have but very common all over the place and just the typical AAA and AA battery charger. Charges 4 at a time. It is timer operated meaning it operates for about 8.5 hours and shuts off preventing over charging. The manual says it will charge 2650mah AA batteries in 8.8 hours then shuts off automatically. I try to deplete the batter as much as possible. The unit's output is 2.8v 360mh . Now I believe also its max charge time is 8.5 hours or auto shuts off at 8.5 hours.
Now, my new batteries ni mh are 3000 mah . Now if you cross mulitply you end up with a 10 hour charge time mathematically, that can be done, just charge 1.2 (or 1.5) hours longer and remember to stop it. But if you factor it differently as the 3000mah divided by the 360 equals the 8.3 hours to charge, not needing the additional charging.

Anyone have experience with these? Just typical rechargable batteries for camera. Any tips on charging these properly?

Thnx 73s

I can contribute only a little: Ni-MH batteries and Ni-Cd batteries are
different as to how they take a charge. While many Ni-Cd's no longer
display a memory effect, some do. As far as I know, there's no memory
effect for Ni-MH. This means you need to treat each type differently.

Would I be out of line to ask you what kind of battery you use and then
narrow the discussion to that type?

Hi Sal

I bought the ones off ebay that came from hong kong in about two weeks. Package of 24 aa batteries and aaa batteries. These are nickle metal hidryde. There shouldn't be a memory like the cadnium ones. These are the 3000 mah batteries and just wondering about charging them with my older battery charger that only explaines about the 2650, so I don't believe my batteries are charging to full capacity. Not even close.

It's a T antenna (top loaded vertical)

Topband_160m_T_Antenna1.jpg

The top wires are a capacity hat. The vertical wire does the radiating.

I have called almost every Henry's and the Energiser's tech line.

Now Energiser cannot advise anything, they only sell batteries up to 2500mah and chargers to same. Now I imagine soon they will be selling 3000mah batteries as Panasonic and so many other mfgs do already. The batter charger I have is obsolete now, 2 years old and actually they still sell it at Henrys.

So I suppose my options are to buy a battery charger that is smart charger that measures through trickle the capacity of the charging battery and shuts off when trickle gets low enough. Or, use this charger and after its 8.5 hour automatic shut off time to pull out then push back into wall plug to add about 1.5 hours of charge and not forget or it will run the cycle of 8.5 more hours and dissapate heat or overcharge the batteries reducing their life.

The batteries measure 1.38 to 1.39 volts after the 8.5 hour plus the extra about 1.5 hours charge. They measure about 1.17volts when empty.

Whats a poor boy to do? Come on Dave, I know you know. And you know that I know that you know that These are for that battery pack for the HT that I use to measure the gnd radiation for my sauna rocks. Very important.

He's an idiot. He doesn't care that his posts are always off topic, and at least
some people doubt he even has a license. He clearly doesn't understand batteries
and charging them, nor much of anything else it seems. Just do what most people
do - ignore him.

Yes, just call the cable company, tell them you will change to satelite
because it doesn't work.

They will do it for nothing and very quickly.

Yep. I have one. Piece of junk. Works only with NiMH. It will kill
a NiCd battery and will overcharge a partly charged battery.
<http://data.energizer.com/PDFs/chdc.pdf>
"Best used with Energizer NiMH batteries."
Note that it's obsolete.

>Now, my new batteries ni mh are 3000 mah.

Maybe, under ideal conditions and with a very small load. Otherwise,
I've never seen a 3000ma-hr battery.

I have a West Mtn Radio CBA-II battery analyzer:
<http://www.westmountainradio.com/product_info.php?products_id=cba3&navcode=/cbaLink1>
I've tested a few of the flea market NiMH batteries claiming to be
3000ma-hr and found them lacking. I'll post the graphs (if I can find
them).

Incidentally, did you know that it requires one or two initial charge
cycles to get an NiMH battery up to full capacity? I didn't believe
it so I ran some tests:
<http://802.11junk.com/jeffl/NiMH/>
It's not much, but it's certainly real. Note that the load was on the
high side at 1C resulting in measured battery capacity lower than
claimed. This is normal, but I was in a hurry.

>Anyone have experience with these? Just typical rechargable batteries for
>camera. Any tips on charging these properly?

If it's only run by a timer, it's a piece of junk. It probably
assumes that the batteries to be charged are totally discharged, and
after 8.5 hrs of charging, will be fully charged. That sucks because
a half charged battery will be overcharged by that method. If the
batteries get warm, they're being overcharged.

What it should do is look for a decrease in terminal voltage,
indicating EOC (end of charge).

Full disclosure: I got my start in radio in about 1965 with an EICO model something CB radio. Ham radio was available, but I was too lazy to study for the license. CB was also cheaper and easier. Many years later, I worked for several companies that manufactured or sold CB radios in addition to their commercial radio products. I also designed a CB paging system (that was never produced). When I owned part of a land mobile radio shop, we also sold and serviced CB radios. It's really difficult to work in commercial radio, and also avoid CB. I don't see how you've made it this far, and missed all the CB history.

While much of the CB lingo is fairly new and amazingly creative, some of it is based on ham radio lingo, which is not so new or as creative. Somehow, I think we missed a splendid opportunity to add our mark on technical slang.

Hi Jeff, Thanks for the info. That pdf is where I learned that this charger only runs for 8.5 hours and it recommends stopping at certain times for certain mah batteries. It works nice for me because I can plug it into 120 or 220 where ever I am. And my batteries are always depleted before I charge them.
Only problem is that I bought the battery pack for my ht and it takes 10 but charger only charges 4.

http://www.ebay.com/itm/160593039544?ssPageName=STRK:MEWNX:IT&_trksid=p3984.m1497.l2649

But the batteries I bought were these ones

http://www.ebay.com/itm/New-Camera-Rechargeable-Battery-8pcs-AA-3000mAh-NiMH-F1-/330538074900?pt=US_Batteries&hash=item4cf59ac314

I have bought these batteries before for my home phones and they work great. The home phones batteries lasts for weeks without putting back on the charger. I guess I am used to the ni cads because I like to deplete 100%, just a habit.

But that charger pumps out 360 ma at 2.8v and if I do the math that tells me they charge completely at 8.3 hours. That falls within the operating range of the charger. Why does the instructions say 8.5 hours for the 2650 mah battery for full charge? Is the charger that innefficient that there is 20% loss? Or were the first couple charges not effective like you said. This is the third charge and the HT emptied quickly. Plus I am now pulling the charger and plugging in again only for about 1.5 hours. Would you recommend that?

Since it is for my HT I would only assume it qualifies for antenna subject,

I am surprised that absolutely none of the dozen local electronic stores and box stores had any idea what I was talking about, even the energizer tech support line were scratching their heads, yet seems so logical a question for me because I want those battery lives to last as long as possible and charging is the answer there. Hense my original question about the charger.

These batteries measure all 1.38 volts when charged pretty consistantly and 1.17v when depleted, other than that I cannot measure the efficiency of the charger to predict time of charge, according to the manufacture it should be 9.9 hours, according to the math 3000mha devided by 360 ma of the unit says 8.3 hours to charge full capacity.

Which is it?

How about this story:

A mad scientist invented the Ultimate Brain Machine. At the press of a
button, he could aim a ray at somebody's head and change their IQ.

First, he tested it on a plumber. He pressed "UP," waited a few seconds and
pressed "STOP." The plumber started quoting Shakespeare and explained
relativity in simple terms.

Next , he tested it on an electrical engineering professor, who was also an
Extra Class ham. He pressed the "DOWN" button and waited a few moments.
Just then, the phone rang. It was a call from his nasty, old wife and he
got into a shouting match with her.

When he hung up, he raced over to the machine, now overheated and smoking.
He pressed "STOP and asked the professor if he was all right.

The professor replied, "That's a big 10-4, good buddy!"

I think I've heard most of it, I just hadn't heard "pill". The short time I was into the CB craze it was in a pretty rural part of northern NY, so maybe that term hadn't made it there.

Ok
So one calles me an idiot, another calls me brainless.

One chap partially answers my question, thank you very much.

What happened to Hams? Used to be such a knowledgeable bunch, still are however there are lots who are wanna bees and you can patrol the newsgroups looking for whatever.

I have a pretty good question here Mark, Robby, just because you don't know the answer, don't make it look like you are smarter than me.

So Robby, you called me an idiot, yet I asked the question, and you haven't any idea about the question. Same to you Mark. Just because you don't know about rechargeable AA batteries, keep your ignorance to yourselves. I am asking, and just because you don't know a thing about AA batteries, well, I recommend either you asking or take a course.

The best thing for you two to do is when someone asks a question, and you don't know the answer, haven't even a clue. Just hang on the side there and watch (or listen) and you will learn also.

I think I may have answered it myself anyway, I am charging for a full charge then about 15% more which re-sets the timer. And I also agree with Jeff, the first few charges in their genisis are important.

So there you go Mark and Robby, see you learned something here today, you can thank me. Why not thank someone who helps you learn, instead you call them names, fling some mud.

Good luck

Hi guys

I think i have answered my own question again. Jeff you are right, the
charger I have is lower end and while good for traveling, it is lmited.

The older chargers aren't suitable for the newer batteries. With 3000 and
3500 mah batteries out now and these older chargers are only good for lower
amp hour batteries, you need the smart chargers. Here is one I am going to
try and will give you all a report later on as to its workability.

http://www.thomasdistributing.com/Accupower-AccuEvolution-Smart-12-Slot-AAAAA-NiMHNiCd-LCD
-Fast-Charger_p_3012.html

If anyone has comments on this charger, I sure would like to hear. Seems
like it is a good smart charger but only runs up to 2900 mah so my batteries
that are 3000 mah may work well.

I didn't say it was limited. I said it was a piece of junk. I have
mine in my digital camera bag, for use only in emergencies.

My favorite cheap NiMH AA charger is another piece of junk that I
picked up at Radio Shock. Model 23-1305.
<http://www.digicircle.com/item_desc.php?make=RadioShack&model=23-1305%2030-Minute%20Battery%20Charger&id=29506745>
Works with AA NiMH only, charges in 30 mins, and hasn't killed any
cells, yet. It's smart enough to recognize that a cell is partly or
fully charged. I erratically retest my NiMH batteries for capacity
loss after charging with my CMA-II battery analyzer. No problems yet.

If you want to do something better, try converting your HT battery
pack to Li-Ion. You'll need an external Li-Ion charger and some
mechanical work, but the resultant huge increase in capacity will be
worthwhile. I've done this for a few home toys (flashlights, alarm
system, battery backup, etc) but have not tried it with an HT. See
model airplane and model auto sites for chargers.

If not, go shopping for an NiMH "smart" charger.

Math always works but it won't give you a good answer if you use bad
numbers.

Here's what I mean: Yes, 360 mA times 8.3 hours equals approximately 3000
mAh but you have overlooked a widely-acknowledged rule for recharging:

Charge at 0.1C for about 16 hours, where "C" is the nominal capacity. Using
that rule, you charge a 3000 mA-h cell at 300 mA for 16 hours. (A battery
maker may impose or recommend something else. I'm parroting what I have
picked up.)

Not all the energy is stored by chemical conversion. Some is lost as heat,
which explains why you need to run the charger longer than you calculated.
(9.9 hours gets you closer but I bet they want to stop short of a maximum
charge to avoid having the cells vent.)

Some support for my views, plus helpful advice here:
http://www.powerstream.com/NiMH.htm

If someone wants to answer an off topic post, that's is up to them, I, and several others don't encourage them by refusing to answer. Your logic(?) is flawed if you think owning an HT that has an antenna means your battery questions are relevant - they are not. That same logic would give you or anyone else the right to ask about an automobile engine simply because the car has an antenna, be it 10, 6 or 2 meter, it doesn't make it on topic. Only an idiot wouldn't understand that.

>What happened to Hams? Used to be such a knowledgeable bunch, still are
>however there are lots who are wanna bees and you can patrol the newsgroups
>looking for whatever.

When you become one, be sure to LEARN about the basics, or at least learn where to go to be on topic. A good general information place to start would be alt.ham.radio but be forewarned, don't ask about your sauna rocks, or any other non-amateur radio related subject, it will only give you away as an idiot or troll. Your "handle" seems appropriate at least. If you are going to insist you are a licensed ham, prove it first. You have certainly provided enough information to prove you aren't. One more time, if your question doesn't relate to the title of the group, don't bother asking there, go to any group that is simply a ham radio group, not an antenna group, not a digital group, nor any other group your question directly relates to, not because you happen to have an antenna in the next room, or a modem packed away in a box somewhere.

>I have a pretty good question here Mark, Robby, just because you don't know
>the answer, don't make it look like you are smarter than me.

Your attempt to egg us on, well, I can only speak for myself at least, will not work. I can't speak for Mark, but I will only state that I most assuredly know about this topic, and let me add, your musings are so far off base, they have been entertaining, if nothing else. I, like many, do not encourage repeated abuse by people like yourself. People who, in spite of being told repeatedly that your posts are off topic in this group, continue to IGNORE those who tried to help you by pointing you to one of the other groups where your ignorance will be hidden from view by virtue of not being off topic. If you continue to ignore this fact, then you are rightly labeled as ignorant. I can only surmise you are either a politician, or a salesman of some sort. A car salesman perhaps? Or maybe a tire, (or do you spell it tyre there) jockey? Oh, and I don't have to be ignorant of batteries, (I am quite knowledgeable in fact) to make it look like I'm smarter than you are, you are proving that just fine all by yourself thank you. You would have been much better off not responding to my post.

>So Robby, you called me an idiot, yet I asked the question, and you haven't
>any idea about the question. Same to you Mark. Just because you don't know
>about rechargeable AA batteries, keep your ignorance to yourselves. I am
>asking, and just because you don't know a thing about AA batteries, well, I
>recommend either you asking or take a course.

Again, your crude attempt to provoke an answer out of me at least won't work. I'll leave it to Mark to give you his response, if he even bothers to give you one.

Speaking of responses, this will be my last, regardless of how much you try to provoke one. I can only speak for myself, but I would hope everyone else here ignores your future off topic posts, as amusing as they might be, they have no place here. If you feel this is unfair, comment about it in alt.ham.radio, or better yet, find a Canadian amateur radio group, perhaps they will have more lax rules.

Come on now Mark Play Nice.

You can't fix stupid!

Handitalkies are for idiots.
WHY?
Because they don't do anything!
Yes they are great for public service events, for hamfests where you want to keep track of each individual person in your group, in emergencies where most communications has been wiped out.

But they suck if you cannot hit the repeaters and their LOS is determined by the size of the ANTENNA, and the height of the antenna above ground.

Two rules of thumb - transmitter range is usually LOS - Line of Sight, even when it is line of sight, the range even for a good antenna is about 1.15 miles per each foot the antenna is held above ground.

Rule number 2 - most educated people, builds repeaters in high places. Mountain tops, tall buildings, on top of tall towers etc....
The repeater by rule of thumb - usually has a hi gain antenna and a transmitter of 10 - 150 watts..

This extends the range of the hand held as well as the repeater.

The funny thing is - most people are so uneducated - they do not realize that the repeater does all of the work.
All that they are concerned with is that they can buy some type of handitalkie for $50 - $250.00 and are free of the expense of a radio, a power supply, a length of coax, a tower or piece of pipe, grounding, a hi gain antenna - which all costs money!

If the only radio a person owns is a handitalkie - they are not HAMS - they are CB;rs....
Why?
Because when MR. Tornado comes to town and wipes out the repeater - they

are of no use to anyone except the local group which handles traffic from the EOC to the hospital, Police, Fire, Ambulance - locally.

Most of those people - because they have no radio experience, is dumbfounded when it comes to putting up temporary repeaters, handling traffic, being of any real value. Because the Handitalkie pretty much reminds them of being on a phone - they end up talking most times as if they were on a telephone. That in return makes us all look bad!

Most times when a emergency does happen, the walkie talkie is still sitting in the drawer - where it was kept for emergencies -with dead batteries and of no use to anyone.

At least the OP didn't waste their money on one of these new Bofung handheld $50.00 radios. Their battery lifespan while transmitting is about 45 minutes max. What does a person do after a hour and a half when both the battery and the spare is dead? They run back to the EOC for another radio or another task to perform.

My personal opinion is that if a person had a GOTA bag with a 50 watt mobile transceiver, a dual band antenna, 6 sticks of 4' fiberglass pole, a ground rod, a 40' length of coax and one of those 850 CCA jump starter battery packs - they could effectively reduce transmit power if needed and could transmit for hours on a single charge. It could be recharged off a vehicle battery, and if it had cross repeat / could be used as a repeater in a emergency to go between the walkie talkies and a more distant repeater...

Nice work Sal

Thats what I am talking about. I knew you had it in ya.

I decided to buy a smart charger, the

http://www.adorama.com/ANCE8.html?utm_term=Other&utm_medium=Shopping%20Site&utm_campaign=Other&utm_source=dealtime

I bought it from a different source at much cheaper the price online
including shipping to my door.

While my other rigs are 1970ish, the HT is mostly for local stuff, the boat,
the company channels, the marine band and the grs bands. Very handy
actually, and practical because programable for a lot of uses. Once it was
opened up.

Thanks for the feedback, sorry for the off topic question and always
appreciate your expertise on here. 73s

My apologies for the group that used to be here.

Many of the people answering lately are not hams.

Those that are will show their calls. Those that hide are not hams.

> http://www.youtube.com/watch?v=zOOihiLLS4I&feature=related

I didn't listen to it for long, but long enough to see that it had no merit.

But, do you think the average ham has a sound understanding?

What about Wikipedia... here is a little extract:

"SWR is used as an efficiency measure for transmission lines, electrical cables that conduct radio frequency signals, used for purposes such as connecting radio transmitters and receivers with their antennas, and distributing cable television signals. A problem with transmission lines is that impedance mismatches in the cable tend to reflect the radio waves back toward the source end of the cable, preventing all the power from reaching the destination end. SWR measures the relative size of these reflections. An ideal transmission line would have an SWR of 1:1, with all the power reaching the destination and no reflected power. An infinite SWR represents complete reflection, with all the power reflected back down the cable. The SWR of a transmission line can be measured with an instrument called an SWR meter, and checking the SWR is a standard part of installing and maintaining transmission lines."

So, from the quote "SWR measures the relative size of those reflections", and when there is no reflection, the "line would have an SWR of 1:1". It is internally inconsistent. This is just as flawed as the videos example of a "radio doin' 10W and only 8W gettin' out, then you have a signal wave ratio of 1.2".

Now, Widipedia started with a fairly correct statement "standing wave ratio (SWR) is the ratio of the amplitude of a partial standing wave at an antinode (maximum) to the amplitude at an adjacent node (minimum), in an electrical transmission line", just someone had to expand that and turn it into gobbledegook.

No wonder people get confused.

And Wiki having given a common formula for VSWR(rho) looks like they considers only a subset of real transmission lines, a rare subset at that, distortionless lines, when they say "As rho, the magnitude of Gamma, always falls in the range [0,1], the VSWR is always >= +1." (Gamma is a complex quantity, yet they specify the range in scalar terms, and it is wrong.)

The difference between hams and chooks is probably one of degree, and becoming less with passage of time.

Owen

Hi David

Batteries for my sauna? Now I never thought about that. 6000 watts ? Now
that is awsome.

I am afraid that the gnd radiation from the granite rocks I used might
interfere with the pulse charging action of today's smart chargers.

But I wonder how many AA batteries would have to be used inline to deliver
6000 watts for about an hours sauna?

You tell me that David and I will tip my hat to ya.

Hi Tom

Thanks for the comment. But I respectully disagree. While I have qso with some of (in my opinion) the most intelligent people I can talk with on the HF and VHF bands. Especially on the HF bands because you must identify yourself regularly. However on the internet I find when you have a conversation with someone they are always asking you what color underwear you are wearing or something stupid like that. Not the same as on my HF rigs. I prefer the HF to the internet anyday. However, I do use this group as a resource for information, my server doesn't give me many newsgroups related to the questions I have asked. But if I ask the question, I get 10 responses, and half of them are flinging mud at me, the other half some useful information I feel good. And I am thankful. And I still say there is a lot of intelligence in here, and I love it.

I learned more about batteries this last week and today's way of dealing with them and I know many readers here did also. Big win win. Crazy thing is, I just refreshed my memory as I learned all this long ago, but forgot it. Damn for braincell degeneration. Anyone recommend anything for that? Scotch and vodka and vitamin b doesn't work. I can contest to that.

But back to your opinion of identifying yourself each time, and identifying yourself entirely. Remember those 50% who fling mud? Well they are capable of anything these days and anonamously throwing rocks through your windows late at night is possible with some of these wackos. So the reason some don't identify themselves all the time may not be because they are not hams, they just want annonamity (spelling?) to keep their guard up as this internet really brings out the worst in some people.

Well, maybe. I don't have a defined sig with my call. I mention my call
periodically in case anybody wants to do a lookup.

643. parts for j-poles

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-01 05:54:03 UTC
From: "Geoffrey S. Mendelson" <gsm@mendelson.com>
Message-ID: <slrnjnfr4k.91u.gsm@cable.mendelson.com>
Source record: 2510

I am going to move in a few months to a new apartment. The best antenna I can put up that I know of at this time is a twinlead J-pole. I need to put up several of them, due to the different aspects of the apartment and buildings being in between some windows and others.

I need advice on sources for the following that will take internet orders, preferaby with paypal and send the items to Israel:

1. 300 ohm CLEAR twin lead. I would prefer current manufacture (assuming it is still made) than 20 year old new old stock (NOS).

25 feet would be enough, but if I had to, I would buy 50 or 100.

2. Thin coax, such as RG-174, preferably in white.

3. Connectors for the coax. BNC would be best. I have tools to apply compression connectors such as used for RG-6, but I have never seen a compression connector for RG-174. Even compression F connectors would be good.

If I can't buy them, then lengths of RG-174 with the connectors already in place would be a ok, but I expect expensive.

Thanks in advance and 73,

Geoff.

Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to

RG-188a/u or Belden 83269 is the PTFE version of RG-174, which usually
has a white outer PTFE jacket.
<http://www.belden.com/techdatas/metric/83269.pdf>
<http://www.ebay.com/itm/130669565253>

The most common crimp connector for RG-174 is an SMA. BNC is also
available. Plenty of both on eBay.

Buy an assortment of crimpers, so you can make your own cables:
<http://802.11junk.com/jeffl/antennas/Misc/slides/crimpers.html>
The green handles are HT-336G crimpers.

I see some on eBay right now... reportedly LEVITON 003-X3300-100,
"new" (dunno if it's freshmade or NOS). Auction 350494793319.

Neither Newark nor Allied seem to carry this stuff in their wire
catalogs any more, as far as I can tell.

>2. Thin coax, such as RG-174, preferably in white.

I'm not sure I've seen RF coax that small, in white. I've seen some
with a clear, or clear-golden outer jacket, through which the silver
braid can be seen... in fact I think I've got a spool of each of these
types. It's fairly stiff compared to a vinyl-jacketed coax of the
same size.

>3. Connectors for the coax. BNC would be best. I have tools to apply

L-com.com and others have these... googling "RG-174 crimp BNC" turns
up numerous sources.

Gotta love eBay, only sold "Buy It Now" for $65/100 feet or $.65 a foot.

Plus they only ship to the US.

Think about it - Net time - those old hams - their knobs are set in stone and they refuse to operate except on that one frequency.
It might as well be channelized.
40 meters - most people won't even turn the knob and you almost never hear anyone yelling CQ - because the net people has their own little channel where they talk and when they are done talking - they shut the radio off.
20 meters on the weekend and evenings is just as bad.

10 meters is so quiet - the only people you get to talk to most times is someone from somewhere else.
Then when the retarded contests comes along - you can barely find a place to talk between 28.300 and 28.500 mhz.

80 and 160 meters at night is just as bad.
All the cussing and swearing and sex talk going on.

Then you have these new hams - the ones with the cell phones, the internet and walkie talkies - because they do not understand how transmitting works and they refuse to spend any money.

At the same time - you can't buy used equipment anymore, because the vultures scarfs up all the used equipment they can find from the SK hams.
Half the times it is sold on flea bay for more then it is worth!

The quality of people - with the CB radio crowd and kids taking it over - it might as well be CB radio.
You can't teach people who's ears are closed and mouths are open.

At the same time, the doors on the old hams houses might as well be made out of solid steel - because very few people gets into their shacks and you definitely don't get to talk on their equipment.

Because the old hams refuses to teach the new hams, and because some of the old hams are lousy LIDS and doesn't know how to operate in the first place - nothing is being taught.

Its hard to teach ham radio to these people who's only radio is a hand held.
What is there for them to learn except how to program it.

I haven't seen it that way over 50+ years of hamming. What I have seen are hams off pursuing their own particular technical interests. Some ragchew on one frequency on 75, and others are always working on moonbounce antennas, etc. Some are heavily involved in clubs and examinations.

You'll find a diversity of activites among hams throughout the years if you look at the overall picture.

Well, of course... I never call CQ on phone.. Only pikers and
people with bad radio breath need to call CQ on phone..

> 20 meters on the weekend and evenings is just as bad.

People have been known to turn off their radios after
operation for years and years..

>
> 10 meters is so quiet - the only people you get to talk to most times is
> someone from somewhere else.
> Then when the retarded contests comes along - you can barely find a
> place to talk between 28.300 and 28.500 mhz.

Well now.. lets see 28.300-28.500.. That's the old "novice"
phone band. Which is a fairly tiny sliver of 10m.
I guess it never occurred to you to maybe bump it up the
band a bit?
>
> 80 and 160 meters at night is just as bad.
> All the cussing and swearing and sex talk going on.

BS.. You will hear very little of this on 160m..
And not nearly as much as you might think on 75..
>
> Then you have these new hams - the ones with the cell phones, the
> internet and walkie talkies - because they do not understand how
> transmitting works and they refuse to spend any money.

What about them? As long as they don't bother me, I could care
less what they do. If they want to prowl the neighborhood with
a belt full of HT's, how would this effect you?

>
> At the same time - you can't buy used equipment anymore, because the
> vultures scarfs up all the used equipment they can find from the SK
> hams.

BS again.. No one is scarfing up anything unless the estate
decides to sell, and they are the ones in a position to decide
a price.

> Half the times it is sold on flea bay for more then it is worth!

Only in America is such a thing possible.. :|

>
> The quality of people - with the CB radio crowd and kids taking it over
> - it might as well be CB radio.

It's obvious that you really don't have a clue.. CB radio crowd?
There is no CB radio crowd, and there hasn't been a CB radio crowd
for many years. I listened to an old E.F. Johnson CB the other day,
when I dug one out of my vast supply of radios, and gave it away
to a friend of mine.
I didn't test it out before I took it over there, but we plugged
it in at his house. It worked. But there was no crowd on the CB
spectrum. :/ You would be lucky to hear a lost truck driver..
BTW, my friend is not a CBer per say.. He just likes to overhaul
these old radios and then sell them on flea bay for vast amounts
of money.

> You can't teach people who's ears are closed and mouths are open.

You also can't teach people who spend all their time channel
jumping..
>
> At the same time, the doors on the old hams houses might as well be made
> out of solid steel - because very few people gets into their shacks and
> you definitely don't get to talk on their equipment.

This is true. I don't want any hairy legged whiners bothering me.
My door isn't steel, but it's fairly thick wood, and I'm quite well
armed. :) So if the door doesn't stop you, I will, when one comes
crashing through it. And I never miss.

But also, you have to consider that if you have seen one shack,
you have pretty much seen them all. :/
Also, I'm generally bored with radio at the house, and spend much more
time tinkering with and flying my 737 NG simulator these days,
than playing with all my radios.
I spend much more time on the radio when I'm at my recreational
living center, than I do at home.

>
> Because the old hams refuses to teach the new hams, and because some of

> What is there for them to learn except how to program it.

Funny.. I had no problem learning about ham radio, even when I
had no ham radios at all.

Have you considered a Digital mode? There are still mindless babblers but at least you don't have to hear them. I run psk31 QRP DX. If I make a QSO it is very short and to the point.

Go to the Radio Shack website. Do a search for "fm dipole antenna".
They still sell them, and they are made of clear 300 ohm twinlead. The
one I have has about a 6-foot feeder, and a 4-foot flattop. Price is
about 7 dollars American.

May I suggest an alternative to a J-Pole? Just build a 1/2 wave
vertical dipole or folded dipole. It's the same size as a J-pole, has
the same gain, is easier to build, and doesn't require invisible
twin-lead. Add a 1:1 coaxial balun for the simple dipole, or 4:1 for
the folded dipole to reduce feed line radiation. The only real
benefit to the J-pole is that it can be end mounted, which is handy
for rooftop mountings. However, for tower, window, cantilevered, or
creative mounting, the center mounted dipole or folded dipole is
easier and batter. As an added bonus, your radiation angle will be
toward the horizon, rather than towards the sky.

Hint: The bandwidth of all of the aforementioned antennas is largely
controlled by the diameter of the wire. If you're only concerned
about a small part of the 2m band, then a thin wire will be just fine.
If you're using high power, or want good VSWR across a wide range for
frequencies, consider going to larger diameter rod or tubing.

><http://www.orionmicro.com/ant/jpole.html>

Thanks,

My reasons for choosing a J-Pole were:

1. I know how to make them and tune them.

2. The clear ones can easily be taped to a window, or glass door, so they don't need any holes to get out.

3. They are bottom fed, so that they can be taped to a window and the coax run along the wall (white) to the floor and then to the radio.

Bandwidth is not an issue, they need to be tuned for 145.025, with a possibility of 145.250. Anything else is gravy, and unlikely to be used.

For example, I currently am using an MFJ "pocket linear" from 1996. This is just a base loaded telescoping whip (I love Jue's marketing prose). It sits on a small Yaseu SWR/power meter and has a 19 inch counterpoise out the bottom.

Works great, has a low SWR and annoys everyone else in the family. So an inivisble antenna and feedline is what I need in the new location. :-)

Geoff.

They don't ship here. :-(

Looking at eBay, the best I can do is $10 for one including postage, which just happens to be the price of 150 feet of brown twinlead without postage, from a US online vendor I found with Google.

Unfortunately the only thing I can find with Google when I search for "300 ohm clear twinlead" is articles telling you to keep twinlead clear of any obstructions, metal etc. I must be looking up to many antenna articles. :-(

Check if you will have Low-E IR reflecting glass, which will block RF.

Try horizontally polarized. After a few bounces off buildings, the
polarization will be almost random.

>Bandwidth is not an issue, they need to be tuned for 145.025, with a
>possibility of 145.250. Anything else is gravy, and unlikely to be used.

No problem. Thin wire will work.

It's difficult to build an invisible antenna. Methinks a camouflage
antenna might be a better solution.

You want end fed. 2nd best would be a coaxial vertical dipole, also
known as a sleeve dipole. Peel off 49cm of outer jacket from one end
of a length of coaxial cable, and fold it over the cable. The exposed
center conductor is the driven element. The coax cable is the other
element. It's a 75 ohm antenna, so there will be some VSWR. Try to
build it with some air space between the braid and the coax outer
jacket. Watch the exposed coax length, as it shrinks as the braid
diameter is "stretched". I build mine with RG6a/u 75 ohm coax
(because it's cheap). If I'm ambitious, I put a plastic sleeve over
the coax, and use aluminum duct tape over the braid.

<http://www.repeater-builder.com/antenna/pdf/qst-2009-07-coaxial-dipole.pdf>
<http://www.hamuniverse.com/vertbazooka.html>
<http://books.google.com/books?id=uxQP2Rfv44MC&pg=SA7-PA23>

Another possibility is to shrink the antenna so that it won't be so annoying. A loop antenna should suffice:
<http://users.tpg.com.au/users/ldbutler/VHFLoopAntenna.htm>
It's very narrow bandwidth, but that's not a problem with your requirements. Since there was only one pair of plates, I build my own butterfly capacitor. Note the voltage across the capacitor.

Geoff, have you considered fabricating a j-pole from solid copper wire?
Yes, it's probably too flexible to be self-supporting from the bottom, as
would a copper-pipe j-pole, but if attached to something rigid, like a strip
of hard plastic, it might work for you.

"Sal"

There is two TNC's on the floor - in a box.
That is probably the best place for them.
As long as people thinks that the only reason for APRS is to play
Where's Waldo - there is no use putting up the antenna and turning it
on.

It looks to me like I hurt some of the forum retards feelings.
I guess there is more then one person on this forum - who's only
transceiver is a walkie talkie or that uses echo link to get their radio
fix - because they are too cheap or too poor to go out and buy a real
radio.

A forum name can be what ever you want.
I could post my call sign - but that wouldn't prove who I am - just that
I am a licensed amateur.
Even that does not tell the whole story - since I have been around this
longer then what most people who calls themselves old hams has been.

The purpose of most nets is to reserve a certain frequency at a certain
time so retards who are mindless and cannot make a QSO or take traffic
can get on the air and say their call sign and no traffic and feel like
real hams.

Most of them goes into panic mode when you try to pass traffic.
Even the PA 80 meter phone and traffic net is mostly made up of people
like that.
So the only thing we can do is wait and see if these people will someday
die off and the net die's due to a lack of participation and we get rid
of many of these useless / unnecessary nets.

What kind of coax has 10 dB loss per 50 feet, and at what frequency?
Those RS amps have no equalization, so the low channels would overlaod
the front end, and the high channels would still be snowy if you need
more than one or two..

So in your transmitters are the coils made of wires?
Where can I find the scheme of a simple todays transmitter with the coils?

I have found this: http://ham-resources.blogspot.com/2011_03_01_archive.html
There is the scheme with the coils.
"L1: L2:
(primary/collector windings) (secondary/antenna windings)
160m--60 turns, tapped at 20 160m-- 8 turns
80m--45 turns, tapped at 15 80m---6 turns"

Does it means that the Tesla coils are in all modern ham transmitters?

No, you babbling moron.

A Tesla coil specifically refers to a resonant transformer specifically
designed to produce high voltages, typically much higher than 10,000 volts.

The coils in radio transmitters and receivers are part of resonant circuits
specifically designed to provide either bandwidth limiting or impedance
matching or sometimes both.

I think Jeff - what the problem is, is that the VEC hands out Ham Radio Licenses like purple Quaalude's at a Grateful Dead Concert.

When your only goal is to increase the number of licensed amateurs, with no concern as to the education portion of the hobby, you end up with a pool of known nothing amateurs, who's only radio set up consists of a single or multiple single or dual band walkie talkies.

Even the local REACT chapter has more money invested in their cb radios and antenna's then the actual amateur radio - Technician Class license holder today.

The burden of proof is the fact that Amateur Radio Clubs in my area are being operated by people who have had their license for less then 5 years, and by people who has no actual real knowledge of how their radio actually works.

The Technology aspect of the club environment has been changed by coffee and doughnuts. " I pity the fool that gets between those club members and the coffee pot when the meeting is over!"

Because of that, most people feels that it is not necessary to join any club, or find a Elmer once you get a license. The people who holds a license isn't qualified to be a Elmer anyways. So basically these people are free to wander the earth, hopelessly lost. Not knowing what purpose Amateur Radio really serves. The ARRL, in hopes of attracting new members, says that the purpose of Amateur Radio is to do Ecom... ONLY Ecom requires training and participation and the use of more then just a simple walkie talkie.

When all else fails - amateur radio still works. - YES
But when all else fails - if your radio equipment does not work - you go hungry, Bow Wow Wow!

People sees something or they read something or they are spoon fed from the QST Magazine they get every month from their membership from the ARRL and they see the articles in the magazine, but the magazines real purpose is to sell stuff. The advertisers is what keeps the magazine going.
I say it over and over again. They are not going to say anything bad about amplifiers - because the first ad you usually see is for some type of amplifier.

People are like Tim the Toolman Taylor - More Power arugh arugh arugh! Only there is no one around willing to stand up on the soap box and tell them that if you have a 100 watt transceiver, to move the S meter one S unit between S - 1 and S-8, you need to increase the power 4 times /

hence you need 400 watts just to move the S meter one S unit.
All signals reduce at the square of the distance away!
1200 watts is only 2 S units.
Yet everyone thinks that with a 1500 watt amplifier, you are going to set the world on fire...
That's only one S Unit - if you were 10/S-9, or two S units if you were less then S-7 with 100 watts...

The stuff that Tesla was doing, would have burned the hair off your head while you stood there and looked at it.
He was able to send electricity through the air for something like 26 miles.
The reason why we don't use Tesla's model of electric transmission is due to the fact that if we did. all we would have to do is stick a antenna up in the air and receive electricity. They wouldn't even have to meter it, because it would be so cheap. The problem is - trying to get these cheap skates to pay for it.

Now think back - gee, stick a antenna in the air and receive free electricity.
Isn't that what we are doing with Amateur Radio?
Or antenna is a electrostatically charged device.
We create power when we transmit and we receive power when we receive someone else's signal..
Maybe what Tesla didn't understand was Broadcasting!
Maybe that was the reason why his coil was dismantled at the start of WW II - because the government knew that if it fell into enemy hands, it could be used to transmit anytime, day or night, globally - any information that someone wanted to send.

Even the largest transmitters of the time - such as WLW's Big Arse Transmitter couldn't compete with the one Tesla built....

So this:

"A Magnifying Transmitter is an advanced version of Tesla's tesla coil, a
high power radio transmitter. Often cited as Tesla's greatest invention, the
Magnifying Transmitter consisted of three coils: an air-core transformer
plus a third coil operated as a grounded-base quarter-wave waveguide. In
Colorado Springs, Nikola Tesla constructed the first "Magnifying
Transmitter". From: http://www.wordiq.com/definition/Magnifying_Transmitter

is not true?

The first person to NOTICE that resonance exists in a capacitor and inductor circuit, thus forming a tuned circuit, was Felix Savary in 1826.

The first patent for a spark-gap transmitter and a receiver with tuned circuits in them was filed by Oliver Lodge in 1897.

Marconi tried to sell his communication system to the US army.
They refused to accept because the system would receive
from all ships simultaneously without selection.
Then he added selective tuneable circuits.

Tesla on the contrary polluted the whole radio band with his
broadband lightning towers and poked fun at those "Hertzian waves".
Tesla never understood and went bancrupt for senile stubborness.

Actually, if you read Tom Edisons Bio - it says that he owed Tesla money
and refused to pay.
Tesla was mad at Edison and said he was so stupid, he was willing to do
something wrong 100 times until he found the right answer, then to spend
the money and pay someone once to show him how to do it the right way.
Tom was the one who was hard headed.
Tesla's family was the ones who benefited by his death.
They were able to settle his estate and collect what was owed to them
and were well off with the money that they received after his death.

Tesla was just stuck on trying to transmit electricity.
If you think about all the money spent on telephone poles, rights of
ways, copper wire etc - if he could have perfected it - it would have
made him a millionaire.

I would chock it up the same as the Tucker Automobile.
It was so far ahead of everyone else - as far as technology went that no
one understood it and the Big 3 refused to allow him to make it, or they
would have had to comply with the standards he invented and it would
have cost them money, both in sales and in market share.

It was easier to get rid of Tucker then to allow him to produce his
automobile and show the world how wrong the rest of the world was.

Things like air cooled engines, seat belts, padded dash boards, recessed
knobs..

My question was:
"Now is 2012. Is " this curious apparatus" the "fundamental part of modern
radio"? Of course in form of the " variations of Tesla coils and Tesla
coil circuits".

In 1924 Marx invented the High Voltage Generator without coils.
Tesla Coil is also HVG.

So I modify may question: "Are in todays transmitters "variations of Tesla
coils" or the "variations of Marx generators".
Or "is possible to do the transmitter without coils"?
If Yes, when was the first?

When you are so obsessed with history, why don't you do your own research?

Asking questions here will never be useful for you because you are not
the type of man to accept any answer.
```

I am not "obsessed with history".

"My question was:
"Now is 2012. Is " this curious apparatus" the "fundamental part of modern radio"? Of course in form of the " variations of Tesla coils and Tesla coil circuits".

In 1924 Marx invented the High Voltage Generator without coils.
Tesla Coil is also HVG.

So I modify may question: "Are in today transmitters the "variations of Tesla
coils" or the "variations of Marx generators".
Or "is possible to do the transmitter without coils"?
If Yes, when was the first?

I have never seen a transmitter (even that in a mobile phone).

Thanks for the link, Dave. Guess I'd heard of Laport's book, but
never seen it. Downloaded it last night, and a quick look this
morning tells me it's a very good book to learn some new things from.

Cheers,
Tom

I wasted a lot of time trying to build a twinlead J-pole. The problem was very limited SWR bandwidth. That's when the idea of making the radiator section thicker came to me - - check out a "Slim Jim Antenna". (I assume you will be using an SWR meter to get the feed tap right.) Good luck on your quest for materials.

None of the above.
```

Modern recievers and transmitters contain coils but by no stretch of the imagination could they be called Tesla coils.

Yes.

Microwave transmitters routinely use resonant devices other than coils and
capacitors.

Dunno.. Transmitting electricity through the air strikes me as
quite lossy, and if using a broad pattern to enable many people to use
it, the amount of recoverable energy vs what is transmitted would be
fairly small. A large amount would go off into space totally wasted.
If his method were actually practical, I suspect someone would be
using it by now on some scale.
There are enough loss just using a direct connection with wire.
I can light a florescent light bulb using the energy from my
HF mobile antenna. But only if I have the tube right next to
the antenna. Five feet away, fugettaboutit..

Exactly why the idea isn't used for anything much heavy duty than charging
a cell phone or a cordless toothbrush.

But system efficiency and losses were not something Tesla took into
concideration, nor was much thought put into how one whould charge
customers when they could have built the "receiver" end themselves
and obtained his electricity for free. Not a viable bussiness model.

I have made only a couple of twinlead j-poles. However, I have made about two dozen from copper pipe. In the course of this, I discovered that no matter what I did with the feed tap, I wasn't getting any to match 1:1 at the low point in-band. About that time, I was reading about the gamma match, whereby the 50-ohm point on one element is fed through a capacitor. The text said it served to null the natural inductance of the elements.

That was an "Aha!" moment for me. The next time I made a copper pipe J-pole, I found my same SWR issue, so after trimming for the best SWR in-band, I placed a 100 uuF cap (100 picoFarads) between connector's center pin and the long side of the J, this in place of a straight piece of wire.

Bingo!

Take it from there, gang.

"Sal"
(KD6VKW)

PS: Weatherproofing the feed point leaves you with an unsightly blob. Tolerable; some days I, myself, am an unsightly blob.

PPS: Don't omit a choke on the feedline, close to the antenna. Otherwise, current on the shield may give you bogus SWR meter readings. Google for <feedline choke> or <feedline choking>.

I do the same when using the base fed 1/2 waves. But I build
them as a ringo, and use a single turn tapped coil, and a length of
coax as the capacitor. Never had any trouble getting a good match with
those. And the value of the cap or length of coax is fairly non
critical as long as you are in the basic ballpark.
Cushcraft used this design, and other variations for a lot of

half wave verticals.
Sometimes with the tapped single turn coil, you can get a decent
match with no cap, but if it's a bit high at it's lowest point, you
can add the cap.
For instance, about 16-17 inches is a good length for 10m. And I
think that is fairly close to 50 pf or so, but I'd have to check.
So for 2m, you could use 20% of that length for a good starting point,
which is about 3.5 inches. BTW, those are for RG-8 type coax..
You might have to adjust for others as far as the pf per foot.

>
> PS: Weatherproofing the feed point leaves you with an unsightly blob.

> <feedline choke> or<feedline choking>.

I used to use radial sets below the half waves for decoupling.
Wide sleeves would probably be even better, but radial sets are much
easier to construct.. :/
I think most of them, I had the radial set 1/4 wave below the
feed point of the half wave element. Seemed to work fairly well.

In an apartment, I'd be about as likely to make a quick
quarter wave ground plane from stiff wire, and hang it from the
ceiling as anything.. For 2m, add a 19 inch wire to the center
conductor, slap a few wire radials to the shield and let them
slope down, stick it to the ceiling with a tack, and you are off
to the races. No matching fuss, and they work within .3 db of the
usual half wave on paper. I've got one in the attic hung from the
rafters. I think I'm using 6 radials on that one. The more radials,
the better the decoupling, if one uses no further decoupling methods
below the feed point.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

Yes. It was impossible to "make" the microwave frequency using coils.
Magnetrons are for it.

But are the modern radio waves (ham) transmitters without any coils?
S*

A coil is made of a wire.
Are "magnetrons" or simmilar device for yours transmitters?
S*

No, it is not "impossible", just more difficult the higher in frequency
you go.

At lower microwave frequencies it is a coin toss whether to use coils
and capacitors or other things.

> Magnetrons are for it.

Magnetrons are not relevevant to the question.

> But are the modern radio waves (ham) transmitters without any coils?
> S*
```

It is possible, at least at low HF, but not practical in general.

You are babbling.

Well, usually but not necessarily.

> Are "magnetrons" or simmilar device for yours transmitters?
> S*

Magnetrons are microwave oscillators and impractical to build much below
1 GHz.

Magnetrons have nothing to do with coils of any kind.

You are babbling.

Jeff is right, inductance would be the correct term but you want a coil made
of wire...Well what do you call a strip line used in VHF & UHF & beyond in
Ham Transmitters...I'm referring to a straight piece of wire (strip line)
that is not a coil & has no turns....Now you have your answer, it is
possible & is done with no coils...Howard K0ACF

The word is inductor. At certain frequencies inductors take the form of
coils. At high UHF the inductors take the form of hairpins (aka Bobby
pins) a half of a loop.

Tesla lives in every old car with a distributor

Many modern solid state transmitters have no "coils", per se, except perhaps in the output low pass filter or output matching network. The carrier is generated from a crystal oscillator (no coils, just caps and a hunk o' rock) and amplified in broadband stages.

Since you haven't a clue what he is talking about, your question is
meaningless.

Most current, modern transmitters, amateur or otherwise, generate their
carrier frequency through digital frequency synthesizers referenced to
a crystal oscillator.

A small percentage of transmitters that are designed for either fixed
frequency use or use over a limited frequency range just use crystal
oscillators.

The output power is produced by amplifier stages to raise the level to the
desired output.

If there were no regulations, that would be the end of it, but since there
are regulations on spectral purity of transmitters, there are resonant
circuits somewhere before the antenna to ensure no spurious frequencies
are transmitted at a significant level.

Below microwave frequencies the resonant circuits are almost always made
of discreet inductors and capacitors forming either band pass or low pass
filters.

Not being led anywhere.

Our little babbling idiot spent a lot of time on the sci.phyics.* groups where he was no better than he is here and his reception was a lot less friendly.

He does not have a license of any kind and apparently not much of an education of any kind other than skimming historical articles on Wiki.

His contact with the real world and every having seen any modern technology of any kind also appears to be extremly limited.

Hi is obsessed with historical stuff, primarily dating from the pre-WWI era.

He is incapable of understanding that any major historical player could have possibly not fully understood everything and have published something that later science has shown to be incorrect.

He can not understand that people like Maxwell, Tesla, Edison, etc. had no access to things that are common today like oscilloscopes, time domain reflectometers, spectrum analyzers, etc.

In summary, he is a babbling idiot.

The problem is most people when they first encounter him treat him like an ernest newbee needing help instead of the fixated idiot he is.

i live in an apt, roof is about 200ft up i have several center fed
dipoles, a end fed /sleve dipole, i also had a small multiband beam
all worked great dipoles were fantastic

good luck

I asked:
"Tesla coil circuits were used commercially in sparkgap radio transmitters
for wireless telegraphy until the 1920s,[1"
From: http://en.wikipedia.org/wiki/DRSSTC

But in 1929 was wrote: "It is not generally appreciated that this curious
apparatus, often associated with pretty or spectacular demonstrations of
high voltage electricity, is really a fundamental part of modern radio. For
all the tuning apparatus and circuits in every transmitting and receiving
set are simply variations of Tesla coils and Tesla coil circuits".
From: http://www.tfcbooks.com/tesla/1929-09-22.htm

Now is 2012. Is " this curious apparatus" the "fundamental part of modern
radio"? Of course in form of the " variations of Tesla coils and Tesla
coil circuits".
S* "

Now I know the opinions of radio amateurs.

Pilots have no trouble using radios at 45,000 ft.
I've never yet seen one require a ground wire.

"Houston, Tranquility Base here. The Eagle has landed,
and we are talking to you via radio, even though we
are not connected to earth, and Marconi said it would
lead to celestial mayhem if we were to even try."

Houston, I we have a problem...

It obviously never was true. My guess is that the reasoning at the time stemmed from a lack of understanding of far-field electromagnetic wave propagation (and electromagnetics in general), failure to construct apparati of sufficient sensitivity due to technology limitations, and inefficient antenna designs (relative to using the earth as a counterpoise.) I also think Nikola Tesla failed to grasp these concepts as well. Sincerely, and 73s from N4GGO,

In the back of the plane there is a small bucket of soil with a ground
rod stuck in it. At each stop they check to make sure the soil is
damp enough to provide sufficient conductivity. On occasion a
little salt is added. The ground rod is connected to the frame of
the plane using an MFJ Artificial Ground to further ensure that
all is well. As well, the bucket is grounded to prevent any
possible cathodic action from interfering with the system.

Marconi added:
"By "connected to earth" I do not necessarily mean an ordinary metallic
connection as used for ordinary wire telegraphs.
The earth wire may have a condenser in series with it, or it may be
connected to what is really equivalent, a capacity area placed close to the
surface
of the ground (Fig. 4).
It is now perfectly well known that a condenser, if large enough, does not
prevent the passage of high frequency oscillations, and therefore in these
cases
the earth is for all practical purposes connected to the antennae."

So the plane is "connected to earth".
Is Marconi right?

A mobile device uses the user as the counterpoise.
A vehicle is not physically bonded to the earth - yet still works.
A Mag Mount antenna is not physically bonded to the vehicle body - hence
it uses a loop radio to antenna antenna to radio and it changes the way
the coax interacts with the antenna.
If the radio is bonded to the body and the antenna is bonded to the body
the body is capacitive. Turns the whole body into one big
counterpoise.

Maybe this is the reason why a 102 inch whip works better then a mag
mount antenna or one of those silly dual sticks on a truckers mirrors...

It was NEVER true; Marconi was wrong.

Here's a news flash for you:

A lot has been learned about radio since Marconi.

The radios on Pioneer 10 worked just fine 12,000,000,000 km from the Earth.

S*
****
No. Spacecraft have no connection to ground, and it is possible to feed
balanced antennas in a fashion that there is no ground connection.

Incorrect. The antennas used do not need a counterpoise. In fact the
user is often a hindrance to the antenna working properly.

It may be more accurate than you are giving him credit for. It was based upon the antenna designs and frequency ranges in use at the time.

All I know is that by the end of WWI, 200 meters was considered to high in frequency to be useable, which is why the US Navy wanted hams to be limited to frequencies above it (or wavelengths below it).

The early practical groundless antennas were 1/2 wave, either a dipole or end fed half wave, and is a 100 meter wire practical? A 1000 meter?

What frequencies (or wavelengths) was he speaking about?

To answer the comment about cell phones, modern ones operate at around 2.1gHz (3G) a frequency that was impossible to produce at the time.

PL-259 connectors are called UHF connectors for a reason, when they were designed 30mHz was UHF. And that was 30-40 years later.

Geoff.

Is even one textbooks where is wrote that Marconi was WRONG?

Are your transmitters without any earth?

I am checking from time to time if your knowledge have moved on.

Hello Szczepan.

In general, you seem to be looking at outdated techniques and technology.

I guess if you were considering photography you would be asking if wet plates were still in use and what would be a recipe for a good emulsion. Of course, film stopped using wet emulsion a century (or more) ago. Wet emulsion wasn't wrong at the time but it definitely is obsolete.

If you were considering car technology you might be asking about manual ignition advance/retard. It had its uses but was automated decades ago and most drivers will not be aware of it. Same thing applies to the choke.

My radio doesn't need to be connected to ground/earth other than for static/lightning reasons. The theory and technology of radio have made a lot of progress since the time of Marconi.

Hope this is of some help.
Kindest regards from the UK,
Ian.

Yeah, it was thought that a long time ago and it has since been proven
to be wrong, as you have been told several times now.

Which means it is true for specific, limited cases, but not true in general.

There has been a lot learned about electromagnetic theory in the past
100 years that this babbling idiot just ignores.

Yes, every modern textbook on electromagnetic theory.

See Electromagnetics by Kraus and Carver, Chapter 14, Antennas and Radiation
as but one example.

> Are your transmitters without any earth?

Yes, some of them are, some of them aren't.

> I am checking from time to time if your knowledge have moved on.
> S*

You are just babbling because you can not accept the fact that a lot was
learned after Marconi died, some of which is in direct contridiction to
some of the things he thought were true at the time.

My understanding is that in this context, "UHF" is not an acronym for
"ultra-high frequency". It means "Universal High Frequency"... as in,
can be used for all "high frequency" applications.

Hello Ian,

So the earth is necessary in your radio for the static reasons.
In my also:
"In the lower half of the mast, there was a vertical steel tube, attached to the mast's outer structure with large insulators. This tube was grounded at the bottom, and connected electrically to the mast structure by an adjustable metal bar at 328 metres.[2] This technique allowed adjusting the impedance of the mast for the transmitter and worked by applying a DC ground at a point of low radiofrequency voltage, to conduct static charge to ground without diminishing the radio energy. Static electrical charge can build up to high values, even at times of no thunderstorm activity, when such tall structures are insulated from ground. Use of this technique provides better lightning protection than using just a spark gap at the mast feed, as is standard at most mast radiators insulated against ground."
From: http://en.wikipedia.org/wiki/Warsaw_radio_tower

It seems to me that the same reasons were in Marconi times.

So I repeat my question:

""The necessity or utility of the earth connection has been sometimes
questioned, but in my opinion no practical system of wireless telegraphy
exists
where the instruments are not connected to earth."(Marconi in 1909).

It is still true?

You have a big problem with comprehending, don't you?
Earlier you wrote that Marconi said that a capacitive coupling to ground
was good for HF grounding and now you want DC coupling to discharge
static electricity. Those two reasons for grounding are completely
different.

> So I repeat my question:

Why do you repeat your question? It has been answered so many
times already.

Radio on the Moon has the "earth connection". The Moon is smaller than the
Earth.
Do you think that "the earth" must be giant?

Your mobile phone has earth connection, radio on satellites and planes
have earth connection because they are on the chassis. Accept this and
move on.
>
> Some antenna systems do have an earth connection, many don't.

All must have.

Each capacitor has the big surfaces and imperfect insulator between them.
Is it the "DC coupling to discharge static electricity"?

" You have a big problem with comprehending, don't you?"

You think "a chassis" is "earth connection"?
What is your definition of "earth connection"?

>> Some antenna systems do have an earth connection, many don't.
>
> All must have.

You are being told NO, by people that know what they are talking about,
and you, the ultimate nitwit, are insisting that it is wrong?

If so, why are you asking the question at all?

On a 628m tall mast, yes. But not on a cellphone.

Marconi explained what the 'Earth Connection' is:

""By "connected to earth" I do not necessarily mean an ordinary metallic
connection as used for ordinary wire telegraphs.
The earth wire may have a condenser in series with it, or it may be
connected to what is really equivalent, a capacity area placed close to the
surface of the ground (Fig. 4).
It is now perfectly well known that a condenser, if large enough, does not
prevent the passage of high frequency oscillations, and therefore in these
cases the earth is for all practical purposes connected to the antennae."

Hello Ian,
#
So the earth is necessary in your radio for the static reasons.
In my also:
"In the lower half of the mast, there was a vertical steel tube, attached
to
the mast's outer structure with large insulators. This tube was grounded
at
the bottom, and connected electrically to the mast structure by an
adjustable metal bar at 328 metres.[2] This technique allowed adjusting
the
impedance of the mast for the transmitter and worked by applying a DC
ground
at a point of low radiofrequency voltage, to conduct static charge to
ground
without diminishing the radio energy. Static electrical charge can build
up

```
# to high values, even at times of no thunderstorm activity, when such tall
# structures are insulated from ground. Use of this technique provides
better
# lightning protection than using just a spark gap at the mast feed, as is
# standard at most mast radiators insulated against ground."
# From: http://en.wikipedia.org/wiki/Warsaw_radio_tower
#
# It seems to me that the same reasons were in Marconi times.
#
# So I repeat my question:
#
# ""The necessity or utility of the earth connection has been sometimes
# questioned, but in my opinion no practical system of wireless telegraphy
# exists
# where the instruments are not connected to earth."(Marconi in 1909).
#
# It is still true?
# S*
```

The answer is still NO. As pointed out by several others, there are gazillions of radios operating without an "earth ground".

If one wants to connect an antenna to ground for lightning protection reasons, that has nothing at all to do with antenna radiation.

760. Electron gun

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-12 16:28:43 UTC
From: Szczepan Bialek <sz.bialek@wp.pl>
Message-ID: <4f8702bc$0$1302$65785112@news.neostrada.pl>

Here is the Tesla's electron gun:
http://en.wikipedia.org/wiki/File:Sp_xmtr.png

"In April 1887, Tesla began investigating what would later be called X-rays
" We now know that this device operated by emitting electrons from the
single electrode through a combination of field electron emission and
thermionic emission. Once liberated, electrons are strongly repelled by the
high electric field near the electrode during negative voltage peaks from
the oscillating HV output of the Tesla Coil, generating X rays as they
collide with the glass envelope. " From:
http://en.wikipedia.org/?title=Nikola_Tesla

So we know that the electrons are liberated from the end of antenna.
But where the electrons come from?
From: "the earth"?
S*

Marconi made an incorrect claim, a claim we now know that is not true.
So, now we are better than Marconi be cause we all (except you) know that.
But that is not surprising after a century of evolution, isn't it.

I wworked for 6 momths for a company that manufactured thin-film optical filters.

The glass pieces were placed ina vacuum chamber. along with the crucible(s) with the coating material(s).

Once the chamber was evacuated an electron beam was used to heat the coating materials, which usually sublimed and were directed magneticaly to the glass.

I still have one of the electron guns (filament burned out). It looks like an oversized tube with an open ended glass tube on one side where the beam was directed out.

So "we" know from you that todays antennas do not liberate even one
electron.

Antennas liberate the EM waves and the electrons as a by product.
Do you support this?

Hello again Szczepan.

The "static to earth" in my HF aerial is merely to get the static to bypass my receiver. The earth connection is not necessary in order to receive signals.

Gordon Bussey, in his book "Marconi's Atlantic Leap", discusses aerials used by Marconi at Poldhu and St John's. He suspects they could well have been capacitive or inductive (page 68). His book is published by Marconi Communications.

I'd certainly prefer to use resonant aerials rather than have a mis-match into a capacitive or inductive aerial. Sometimes the option to use a resonant aerial is not available for me - such as on 160m.

I have a recollection that Marconi didn't (or couldn't) determine the wavelength / frequency he was using. This makes it difficult for us to accurately determine the match or mis-match of his aerials and radios. I also recall debate in the 1970s as to whether the three dots really had been received or had been imagined. There was conjecture that the aerials and frequency used probably used would not propagate across the Atlantic successfully.

Look at Baird. He demonstrated successful transmissions of moving pictures via radio. It worked (and I believe it offered colour and 3D) but it soon became obsolete due to the superior EMI system. Similarly, Marconi demonstrated the practical use of wireless by keying a spark transmitter. These days we no longer use spark (and we do a lot more with a radio signal then key it on and off).

It also has to be remembered that Marconi brought a lot of existing technology together to form wireless / radio. For example, according to Wikipedia induction coils date back to Faraday and Ruhmkorff.

So, no, an earth is not necessary to transmit and receive radio signals. Was Marconi wrong? Let's say that he could (and probably would) have done better if he understood radio as we understand it to-day.

Kindest regards, Ian.

Hello Ian,

See the topic "Electron gun".

Each antenna liberate EM waves, heat and electrons.
At the end of the mast the voltage is dobled and the "field emmision" works.

The heat is no problem but the escaping of electrons is a problem.
Tesla discovered that the one end of the dipole must be earthed to have the
strong waves.

That should be obvious for you.

"The earth connection is not necessary in order to receive signals."

It is necessery to transmit and to receive.
You have it: "The "static to earth" in my HF aerial is merely to get the
static to bypass
my receiver".

The liberating of electrons by a transmitter and absorbing by a receiver is
a by products of antennas.
The "earth connection" is a remedy.

Best Regards,
S*

All who know what the "field electron emission" is.

"Introduction.-The main features of t h e phenomenon of the
extraction
of ele&ons from cold metals b y intense electric fields are well
known,"
From:
http://www-project.slac.stanford.edu/lc/wkshp/RFBreakdwn/references/fowler.pdf

Each metal with the excess of electrons liberate them.
A transmitter antena liberates radio waves, heat and electrons.

Waves travel in space, heat is dissipated and electrons are taken from the
earth.

There are no electrons "liberated" on a transmitting antenna unless
something is arcing and it is an abnormal condition.

There are no electron absorbed by a receiving antenna.

You are a babbling idiot.

> The "earth connection" is a remedy.

Only if that "earth connection" is you 6 feet under it.

We, being anyone with any knowledge of electromagnetics, know that
antennas do not liberate or emit any electrons under normal conditions,
either today or any time in history.

If an antenna is emitting electrons, something is arcing, which is NOT
a normal or necessary for radio transmission.

> Antennas liberate the EM waves and the electrons as a by product.

No, they do not under normal conditions, now or ever.
```

> Do you support this?

Of course not as it is babbling gibberish.

Tesla was playing with Tesla coils and extremely high voltages which produced RF energy as a by product.

Producing RF energy through arcs and sparks is a technology that was abandoned about 100 years ago.

Hello again Szczepan.
I'm sorry to say that I didn't understand this part of your posting:
"Each antenna liberate EM waves, heat and electrons.At the end of the mast
the voltage is dobled and the "field emmision" works. The heat is no problem
but the escaping of electrons is a problem."
Do you mean "mast" or "aerial" when you say that the voltage is dobled
(sic)?

"Tesla discovered that the one end of the dipole must be earthed to have the
strong waves."
This is definitely something that I will not be doing. A dipole has low
impedance at the feed point and high impedance at its ends.

Best wishes, Ian.

Not dobled but doubled (twice as large). It is desribed by Lodge: See Fig.2
: http://www.antiquewireless.org/otb/lodge1102.htm
"The electrical waves produced by the oscillations at A traveled along the
wires and were reflected at the far ends. Lodge knew that the longer spark
at B3 was due to what he called the "recoil impulse" or "recoil kick" at the
end of the wires where the waves were reflected.[4] At spark gap B3 both the
incident wave and the reflected wave had their maximum values and were in
phase. This produced a voltage twice as large as the voltage at spark gap
A."
>
> "Tesla discovered that the one end of the dipole must be earthed to have

A dipole with one ene earthed becomes a monopole.
Hertz transmitter is a dipole. The Tesla's is a monopole.
Todays dipoles are simply the two monopoles.
Thanks this the waves are polarized.

But the question is if Marconi was right:"
"The necessity or utility of the earth connection has been sometimes
questioned, but in my opinion no practical system of wireless telegraphy
exists
where the instruments are not connected to earth."

Best regards,
S*

The problem with you is that you will not take the correct answer
to that question, but you will keep asking it until someone incorrectly
answers that Marconi was right.

Ian did it. He wrote:
"The "static to earth" in my HF aerial is merely to get the static to bypass
my receiver. The earth connection is not necessary in order to receive
signals."

Tell as if a practical radio exists where the instruments are not connected
to earth/chassis."
I am not asking for what: to bypass or to receive/transmit.

S*

Hello Szczepan
No, I did not say that Marconi was correct. I did say that the earth
connection is not necessary in order to receive signals. I suspect that your
English is not as good as we think.

Voltage is not product. The splendid, long sparks are.
What the sparks are made of?

I have even never seen a transmitter.
For me it is a "black box".

I only want to know if the box is connected to the earth/chassis.

Your the first answer was Yes ("The "static to earth" in my HF aerial is
merely to get the static to bypass my receiver).

Hey Szczepan,

Spark transmitters are not used anymore.
Try to find some more recent articles about transmitting.

Today we use nicely synthesized carrier waves that are fed to
antennas suitable for the frequency in use, not a noise generator
and transformer to high voltages connected to a random wire net.

Especially when that frequency is somewhat higher (much higer
than what Marconi and Tesla were transmitting on), there is no
need for en earth connection or even a chassis.
That is because an antenna is used that is balanced or has its
own counterpoise for the driven element.

A connection to earth would not be effective anyway, because
antennas used at higher frequencies are often several wavelengths
above the earth, and a wire used to connect to the earth would
not behave like a conductor at those frequencies.

We also operate our antennas well below the point where arcing
occurs, so we don't have to deal with electron emission.

So now please go off to a group that operates the century old
techniques that you seem to be discussing.
Maybe you can find a Tesla coil enthousiasts group where your
voice will be appreciated, although I think they are not using
sparkgaps anymore either.

That his English is horrible is a given, but since he has been doing exactly the same thing for years now it should be a lot better than it is.

He has been posting the same idiotic crap for years to the sci. groups and getting the same responses.

He is incapable of comprehending that Tesla, Maxwell, Marconi, etc. did NOT have a full understanding of RF over a hundred years ago.

He keeps posting the same idiotic questions, with references to century old quotes, over and over no matter how many times he is answered.

> Szczepan - do you hold an amateur radio licence, please?

No, he does not.

Yes, it is. The purpose of a Tesla coil is to generate high voltages.

> The splendid, long sparks are.

Nope, the purpose is the high voltage, the sparks are a by product of a
high voltage.

The RF produced is a by product of the sparks.

The high voltages produced by the Tesla coil.

Repeat this until it sinks into your thick skull: Tesla coils produce high
voltages.

Repeat this until it sinks into your thick skull: High voltages produce arcs.

Repeat this until it sinks into your thick skull: Arcs produce RF.

Repeat this until it sinks into your thick skull: Using arcs to produce RF
is an obsolete techonology and illegal in most of the world.

Hello Szczepan.
It seems that you totally misunderstood my answer.
A ground connection is NOT necessary in order to receive a signal.

You tell me that you have not seen a transmitter and regard it as a black
box. I recommend that you get a modern textbook on radio technology so that
you can understand how radios and aerials work.

Kindest regards, Ian.

Hello again Szczepan. I rarely ever use the term "chassis" and I don't
remember mentioning an earth on a radio.

For clarification - radios can and do transmit and receive successfully
without any connection to earth, either the actual ground or to an
artificial earth.

Kindest regards, Ian.

Source record: 2336

Well I am going to be unusually kind today, since it is Sunday and also because I am going to show some intelligence here. So everyone listen up - because I am only going to do this one time.

I am not going to fight over who invented radio, or the different types of modulation scheme's - since the days of spark gap transmitters.

I tried to post some relevant information - but it seemed to get lost in the jumble.

The bottom line is - 3rd world countries and places such as the Soviet Union and their sattelite countries does not understand how communications works - to the extent that people in the free world does - because when you live in a communist society you are told what to think and how to think and so you cannot think for yourself.

When the day comes when someone emancipates you and you are free and all of a sudden there is no one telling you how to think or what to say - your mind goes beserk and you just start thinking about things that no one has thought about in 50 years - because even a infant has to crawl before it can walk and those people are so far behind the times it will take them a certain period of time to readjust to the way the rest of the world operates and so we have to be kind to people who were not born and raised in the USA and thinks that they are the worlds leading source of all information and that everything published on the internet is factual.

The Sattelite one was the one that really got me to thinking.
There is nothing in outer space for the signals to bounce off of - so they travel millions of miles in just a couple of seconds and you have to wonder if there is some other form of intelligence on another planet several galaxies away that is monitoring our simple form of communications - and probably laughing at us for what we say and how we act and what we do.
Rock n roll music is probably the most entertaining of all the types of transmissions we make - because it doesn't make much sense when some rapper repeats the same thing over and over again and other musicians plays the same 3 chords over and over again and people pays millions of dollars to buy their albums and listen to them at concerts or that we would allow someone to play advertising over the radio and not turn it off or turn the dial to another frequency.

Or that some ham would be willing to spend 10's of thousands of dollars to buy a transceiver that does the same basic thing as a AM radio you can buy in any Walmart or Goodwill for a couple of bucks.

When you crank up the power, it allows the person on the other end to use a smaller antenna - hence the people who buys or builds the big towers and the big beam antenna's would think that their investment would allow them global communications on a daily basis - and still we have not gotten past the fact that all reliable communicatiosn is LOS - even 100 years later...

The OP wanted to debate the fact that some antenna's works best when we include some type of ground. Yes a good vertical transmitting antenna includes some type of ground to keep the signal from warming the clouds and being wasted.
A beam antenna does not have a physical ground, yet still works - maybe the ground reflections helps the signals to travel further.
But we all know that effective communications requires the antenna to be as high as possible.
Only once you get to what is it 38,000 miles one antenna will transmit to one hemisphere - or is it what ever part of the earth you can see and will transmit no further.
That is the point of diminishing returns.

For me is enough to know "Is it the ground/chassis/counterpoise necessary to
"get the static to bypass a transmitter/receiver".?
I hope that some of you know the answer.

I am not asking If "Does a ground connection is necessary in order to
receive a signal."

Best regards,
S*

"One side of the antenna feedline is attached to the lower end of the monopole, and the other side is attached to the ground plane, which is often the Earth.

This contrasts with a dipole antennawhich consists of two identical rod conductors, with the signal from the transmitter applied between the two halves of the antenna.

Any comments?

Now you have written it yourself! With a dipole antenna you do not
need an earth connection because the signal is applied between the
two halves of the antenna, not between earth and the antenna.

End of discussion.

It says "for AM broadcasters", not "for every transmitter".

Your conclusion that anything applying to a low frequency transmitter
for which it is impractical to build a balanced resonating antenna
applies to all transmitters in the universe is just wrong.

Hello Szczepan .
Dipole has two pieces of metal.
Monopole has one piece of metal.
Connecting a dipole to ground doesn't remove one piece of metal.

Best wishes, Ian.

No.

Read this:

http://en.wikipedia.org/wiki/Field_electron_emission

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Corona_discharge

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Electric_arc

Read all of it.

Then read it again until you understand it.

If you can get this far, your question has been answered fully.

Real dipole needs:
"In the lower half of the mast, there was a vertical steel tube, attached to
the mast's outer structure with large insulators. This tube was grounded at
the bottom, and connected electrically to the mast structure by an
adjustable metal bar at 328 metres.[2] This technique allowed adjusting the
impedance of the mast for the transmitter and worked by applying a DC ground
at a point of low radiofrequency voltage, to conduct static charge to ground
without diminishing the radio energy. Static electrical charge can build up
to high values, even at times of no thunderstorm activity, when such tall
structures are insulated from ground. Use of this technique provides better
lightning protection than using just a spark gap at the mast feed, as is
standard at most mast radiators insulated against ground."

Hello again Szczepan
The answer to your question is in that Wikipedia article. Read the
"Radiation Pattern" paragraph.

If you can get ham radio textbooks in your country then you'd understand a
lot better by reading a textbook on aerials.
Try www.rsgbshop.org/acatalog/Online_Catalogue_Antennas_37.html
and www.arrl.org/shop/Antennas/

I haven't seen an answer from you to my question which asked:
"Are you discussing resonant or non-resonant aerials, please?"

Best wishes, Ian.

Good evening Szczepan.

The Warsaw radio mast was not a dipole.

May I remind you that I would appreciate an answer to my question "Are you
discussing resonant or non-resonant aerials, please?". It would help to
clarify what you have in mind,

Kindest regards;
have a good evening,
Ian.

That is not a dipole. It is a vertical half-wave radiator. It is
not center fed like you discussed above.

Because they are talking specifically about a vertical, monopole antenna
mounted on the ground and fed at the base end.

They are NOT talking about antennas in general.

They are NOT talking about transmitters.

> Tell them that they are WRONG.
> S*

They are not wrong, you are just too stupid to understand what they ARE
talking about.

Good evening Szczepan.

Your question "What the sparks are made of?" was answered in the posting
from jimp @ specsol.spam.sux.com dated 15 April 2012 17:06.

Are you having difficulty reading or understanding the emails send by others
and intended to enlighten and inform you and answer your search for
understanding?

Have you looked at any of the books I mentioned in an earlier posting,
please?

Kindest regards, Ian.

Use a static electricity dissipator:
<https://www.google.com/search?q=static+dissipator&tbm=isch>
Commonly found on airplane wing tips, fiberglass hull vessels, and
ungrounded towers prone to lightning hits. A 1M resistor to ground
will discharge any static build up across a base insulated tower.
<http://www.lbagroup.com/international/tower-lightning-protection.php>
<http://www.lpsnet.com/ALS.asp>

I'm not sure why you're arguing about grounding antennas. There are
plenty of examples of antennas that operate without a ground. If low
frequencies are your immediate concern, may I point out that DF loop
antennas are very popular on the beacon bands (200-400KHz). They also
work nicely in airplanes, where there's no available earth ground. BCB
is no different. There were plenty of antique home receivers that
used either an internal or external loop (or loopstick) antenna, that
didn't require a ground connection.

If BCB stations decided to use horizontal dipoles instead of vertical
monopoles, a ground would not be needed. The only reason they need a
ground is to act as the counterpoise for the monopole. This provides
the missing 1/4 wave element of the dipole.

That's about one silly statement, unless the ham plans to do
nothing but listen to KTRH all day long. Most use them in other ways,
which most all of which the typical Wallace World special could only
dream of. I only wish Wallace World sold usable amateur radios for a
couple of bucks.
I'd have several hundred more radios than I already have. :|

Not all verticals require ground systems, and how did the clouds
ever get involved?
Seems you may be confusing the benefits of feed line decoupling
with the benefits of a radial system under a ground mounted monopole. :/

> A beam antenna does not have a physical ground, yet still works - maybe
> the ground reflections helps the signals to travel further.

Then maybe they don't.. Also, some directional arrays do use ground
systems, if they are ground mounted.
But this statement does not mean Marconi's statement is correct.

> But we all know that effective communications requires the antenna to be
> as high as possible.

In some cases, it may make no difference how high the antennas are.
In others, it may mean a great deal.

> Only once you get to what is it 38,000 miles one antenna will transmit

> That is the point of diminishing returns.

Maybe so, but there are no structures that high for me to
attach an antenna to. And I can't jump that high. :(

837. any Boca FL area Hamfests

Consider what you find at n3fjp.com. I'm the local club's FD chairman and
we're going to use his network logging program this year. Our trials with
Field Day Logger 2.6 have all been satisfactory but I have no experience
with any other programs.

In the statement about AM Broadcasters you state about the ideal ground system & describe about the Radials but then ask why, That goes to show you don't know anything about Antennas, Transmitters. Feedlines, Matching, Efficiency, If you read farther you would have possibly learned something but you don't want to learn just bother the group. Nowhere in what you wrote does it state it is for static or what it is for except if you would read farther it would have told you...What about a balanced antenna, It has no earth connection & doesn't need one per your earth definition. If Maxwell was alive today & had read about all the improvements & discoveries that have been made & are still being made He would say He was wrong & that the answer to your question is NO.....I see you have started a new thread called Electron Gun but keep referring back to this thread for the answer. I'm very sure you know nothing about a electron gun, or a vacuum tube....To bad you don't know how to read or study & especially learn about anything...

Good morning Szczepan.

I think we have a language problem here. The answers to your questions ARE in the books that I mentioned. If these books are not available in your native language then I can understand your difficulties.

I recommended the amateur radio books because they cater for people who have no prior knowledge of radio and aerials.I still haven't seen an answer from you to my question "Are you discussing resonant or non-resonant aerials, please?".

Kindest regards, Ian.

It seems to me that you do not know what the word "resonans" means.
We are discusing the earth/chassis/ counterpoise and the field electron
emission.

Hello Szczepan.
If you mean the Warsaw radio mast (
http://en.wikipedia.org/wiki/Warsaw_radio_mast) then you are incorrect. It
was not a dipole. Do you mean another tower which supported a dipole aerial?

I assure you that I do know the meaning of "resonant". I need to know and
understand it in order to match my radio to my aerials.

Kindest regards, Ian.

I am not arguing. I agree with you that " they need a ground is to act as
the counterpoise for the monopole."
I hope that you agree with me that monopole on the plane/satellite has the
counterpoise in form of chassis.

You claimed that ANY transmitter with ANY antenna ALWAYS needs an
earth connection. That is incorrect. If Marconi claimed that,
Marconi was wrong.

Now you are more and more restricting the playing field by talking
about AM transmitters, monopoles, etc. And by extending your
definition of "an earth connection" to a chassis.

This of course leads to nothing. The original claim is still wrong.

Not. There is no electron emission from an antenna when operated without
arcing, something that everyone except Tesla wants to avoid at all times.

The original Marconi's claim was:

In 1909 Marconi wrote:
http://www.nobelprize.org/nobel_prizes/physics/laureates/1909/marconi-lecture.pdf "The necessity or utility of the earth connection has been sometimes questioned, but in my opinion no practical system of wireless telegraphy exists where the instruments are not connected to earth.""By "connected to earth" I do not necessarily mean an ordinary metallicconnection as used for ordinary wire telegraphs.The earth wire may have a condenser in series with it, or it may beconnected to what is really equivalent, a capacity area placed close to thesurfaceof the ground (Fig. 4).It is now perfectly well known that a condenser, if large enough, does notprevent the passage of high frequency oscillations, and therefore in thesecasesthe earth is for all practical purposes connected to the antennae."Is the original claim wrong?S*

In the early days of radio, most experimenters tended to think of antennas as working by RF alternating currents charging (and discharging) a big capacitor in the sky via a long, vertical wire (or multiple wires, to increase the capacity, and to minimise losses).

To push and pull the current in and out of the capacitor, it was necessary to have a good, solid, zero-potential reference point, and the best one available was ground/earth (or, at sea, the hull of the ship). So, for the types of antennas being experimented with (and used) at the time, Marconi was absolutely correct.

Also, it wouldn't have taken them long to appreciate the benefits of bringing the antenna system to resonance on the frequency the operators wanted (rather than it simply being an act-of-God and hope-for-the-best affair).

But note that with Marconi's famous crossing the Atlantic experiment, I believe there is no documentation of exactly what frequency was used. Instead of it being something extremely low (which is what they expected), it is now thought that the signal which travelled 3000 miles would have been one of the many harmonic resonances of the antenna, as this would have been excited by the extremely wide band of frequencies created by the spark transmitter. Knowing now what frequencies cross the Atlantic in daylight, the signal might have been as high as 10 or 15MHz (frequencies which Marconi only dreamt about using!).

Not true. At higher frequencies, one can use the grounded coax cable
feed to act as a crude counterpoise.

>I hope that you agree with me that monopole on the plane/satellite has the
>counterpoise in form of chassis.

No. You claim that because the monopole requires a ground, therefore
all antennas require a ground. That's too general a claim and is not
true, even for a monopole. For example, a very common antenna type at
2.4GHz is a "meandering 1/4 wave" antenna, which uses no ground:
<http://802.11junk.com/jeffl/antennas/laptops/slides/compaq-2120us.html>
Another example is the metal rim of the iPhone 4G. It's an untuned,
ungrounded, end-fed, monopole in the form of parts of a metal frame.

There's also a large distinction between a "ground" and a
counterpoise. A counterpoise is a part of the antenna system and may
be earth ground in some situations. In RF, a ground is a connection
to the earth. While there is some overlap in these definitions, your
claim, that all antennas require a ground, was presumably referring to
the earth ground, as described by your examples of broadcast towers
and static buildups.

For a satellite, there's may be a counterpoise, but no (earth) ground.
The counterpoise is unlikely because most satellites use circular
polarization (to eliminate sensitivity to orientation), using spiral
wound or pyramid shaped antenna structures that are matched to
whatever the coax cable provides. The skin of the satellite is
crammed with other antennas, solar cells, and sensors, that finding an
area sufficiently large to be considered a metal counterpoise, is
impossible.

The only thing really necessary for an antenna to function is the
radiating element. Everything else is optional and depends on what
you're trying to accomplish.

It does NOT require a ground to be functioning, assuming the energy is
coupled into the radiator using some other way than an end-feed.

Of course it would be stupid to erect an over 600m high mast and not
connect it to ground, but that is for reasons entirely unrelated to
its use as a transmitter antenna.

The tower insulated half way up and feed there are the two monoples.
It is the array.
But such are in form of the two monopole mast 1/4 wave apart.

Will be better to end the discussion.

Yep.. I think the frustration tends to be difficulty in understanding
that it's just one type of system, and others that do not require any
ground connection do exist.
Which means you would have to classify his statement as incorrect in
the overall larger picture. I believe most have already stated that
while some antennas do require such a connection, any "complete"
antenna does not require one.

The vast majority of my antennas do not require any ground connection
for proper operation.
Fer instance, I'm sitting out in the woods up at my recreational living
center.. I have dipoles strung up in the trees which I leave there,
and I roll the rg-58 coax up and hang it on a tree branch when I leave.
Not a ground wire, or ground connection in sight.. And works perfectly
well. Of course, you can't really see the wires here, but "S" can trust
me, there is no ground connection. The radio is sitting on that stone
bench, and the only connections are 12v to my car battery, and rg-58
coax feeding the dipoles. "I have 80 and 40 meter dipoles fed parallel
with a single coax, and can slap a tuner on it, if I want to use some
other band. " I have videos of this radio session using almost every
band from 80m to 10m.. I went through each one seeing if they were
active. They all were, up through 10m, on that day. If one wants to
hear another band, just change the "80" in the url to "40", 20", "17",
etc.. I think they should be on the server.. I think I missed 12m
though for some reason.. Maybe no one was talking when I tuned it..
But it was open to somewhere, as I recorded Rarotonga Islands on 10m.

It wouldn't surprise me too much. Heck, I've been faked out more
than once when using cheap receivers, and picking up something that
was actually not on the frequency that I thought it was. :|

Correct.

One interesting counter-example, would be the simple one of a
full-wavelength loop of wire, which is fed with a balanced feedline
(twinlead or open-wire or ladder line), which is fed from a
fully-balanced transmitter output stage (e.g. with transformer
coupling from the driver transistors). To be extreme about it, let's
say that the transmitter is itself based on a fully-balanced
(differential) circuit, all the way back to the crystal oscillator.
It's powered by a single battery, and is installed in a plastic chassic.

This sort of antenna would have no galvanic connection to "earth" at
all. Measure the resistance or RF impedance between any part of the
antenna or feedline structure, and *anything* not part of the antenna,
and the result will be "huge".

Since it's a loop antenna, it has no "ends"... no points at which
electrons could "fly off". The net current flow going up the feedline
to the antenna will be zero, at all points - a positive current on one
side of the feedline will be exactly balanced by a negative current on
the other side of the feedline. There are no "excess" electrons or
charge flowing in either direction.

You can even insulate the antenna wires, if you wish.

It will transmit just fine, with no connection at all to "ground".
Disconnect the transmitter, install a receiver of a similar "balanced
and isolated" design, and it'll receive just as well... again, with no
connection to "ground".

I think he's the same guy who, for several years, has been posting
similar nonsense in various newsgroups. The script is usually similar,
typically "I have only a very basic knowledge of physics, but I know
that Einstein was completely wrong about his theory of relativity".

Well, this one usually goed more like "I read that in 1910 this result
was found in experiments, so everything we learned after that must
be completely wrong"...

A loop antena have the antinodes. The points at which electrons could "fly
off".

See Fig. 2: http://www.antiquewireless.org/otb/lodge1102.htm

>The net current flow going up the feedline
> to the antenna will be zero, at all points - a positive current on one
> side of the feedline will be exactly balanced by a negative current on

""A further feature of the structure of negative coronas is that as the
electrons drift outwards, they encounter neutral molecules and,
withelectronegative molecules (such as oxygen and water vapor), combine to
produce negative ions. These negative ions are then attracted to the
positive uncurved electrode, completing the 'circuit'.". From: Negative
coronas. Mechanism.
http://en.wikipedia.org/wiki/Corona_discharge#Negative_coronas

In the each antenna is the excess/deficit of electrons and "charge flowing
in either direction."
But the negative corona and the positive corona are not simmetrical.
At transmitting you have the deficit and at receiving the excess.
Without the earth the static build up and radio stop working.
>
> You can even insulate the antenna wires, if you wish.

Can you measure the static electricity?

You will transmit just fine if you have the ground/chassis/counterpoise.

We don't operate our antennas in the voltage range where that becomes
a problem, like Tesla did.

So it does not apply to amateur radio antennas.

Hello Jeff.

I agree. It's nice to see there are some patient and helpful people on this NG who have tried to help S. I'm speculating on what sort of person he really is .. then I smile to myself when I see his circular arguments. I wonder what would happen if we posted items about him but didn't reply to his postings (similar to the "we're talking about you, not to you" behaviour".

I'll tell you one thing - the discussion about antennas has been very interesting so it's made the NG live up to its name.

73, Ian.

I doubt that he is a troll. Trolls usually show some intelligence in adapting their responses, so as to keep the fun going. This one simply fixates on a few sentences and appears unable to focus on anything out of the immediate context of the original sentence. This inability to shift focus to process new information is more a symptom of a cerebral handicap, something like Alzhheimer's or Asperger's diseases or even early-stage dementia. Unfortunately, there is not a great deal that medicine can do for these problems. Perhaps his keepers give him a computer to occupy his attention.

Internet newsgroups are wonderful (IMO), but there are not good mechanisms to prevent one or two people from destroying an otherwise excellent group. One can plonk the offender(s), but that still leaves all the responses visible. I wish people would simply cease responding to him, since it is a pointless exercise.

Bill

What happens on antennas is NOT "field electron emission" by the modern
definition of the term.

Corona discharge is something else, related, but something else.

Hello chaps.
Several of you have said that Szczepan seems unable to accept new ideas.

I see that he persists in believing Marconi's comment that an earth connection is necessary. Those of us who use Yagi , loop or dipole aerials know, through experience, that an earth connection is not necessary.
I am undecided why he prefers to believe the opinion of someone who worked in the early days of radio rather than those of us who use radio in modern times.

I feel it is awkward to say that Marconi was wrong even though we now know this is the case. Personally, I'd say that Marconi's opinion that "no practical system of wireless telegraphy exists where the instruments are not connected to earth" obviously related to his own use of wireless. As I understand it, Marconi's aerials were not resonant at the frequency he was using. They would therefore be a mis-match to his radios and this situation was alleviated by using connections to earth.

I find it puzzling that Szczepan feels happy to ignore our comments and continue to accept Marconi's opinion given that he (Szczepan) said that a transmitter is a "black box" to him. I've speculated that his English may

not be very good but I shall be amused if we find out that his first language is English despite his non-English name.
He never answered my question about resonant / non-resonant aerials so I guess his technical knowledge is limited.

Kindest regards to all,
Ian.

ps: If Szczepan is happy to constrain his knowledge to the days of Marconi then I wonder how come he is using a computer. Didn't have those in the days of Marconi.

Why?

A lot more has been learned since 1887.

<snip>

> Can you measure the static electricity?

Sure, with a static meter.

Yet another device that didn't exist in 1887.

> You will transmit just fine if you have the ground/chassis/counterpoise.

It depends on the type of antenna.

If it is a dipole, yagi, log-periodic, sturba curtain, rhombic, parabolic,
helix, loop, cubical quad, on any of many, many more types of antennas
that have no place or need to connect a ground, it would not.

Marconi was wrong.

Most of the antennas in use today were not invented until after Marconi.

Marconi would be totally baffled if he were shown a helical, yagi or slot antenna.

No.

You did not read the material.

From http://en.wikipedia.org/wiki/Field_electron_emission

"Field emission in pure metals occurs in high electric fields: the gradients
are typically higher than 1 gigavolt per metre and strongly dependent upon
the work function."

Do you have any clue what it takes to get a gradient of 1 gigavolt per metre?

Little of the technology in use today was known in Marconi's time.

Marconi knew nothing of resonance, impedance, or electromagnetic field
theory; it all came after his time.

Marconi would have been totally baffled if shown a helical, slot, yagi,
or any number of antennas invented after his time in common use today.

The only reference antenna Marconi had was a wire of some sort fed against
ground.

For that particular type of antenna, Marconi was correct, but his statement
is NOT correct for antennas in general.

Hello again.

I bet that Marconi would have been very wiling to learn about new theory and
technology ... unlike some people.

Regards, Ian.

I would also bet Marconi would not stubornly cling to something said a 100
years before his time as being absolutely correct.

IMHO the guy is just jerking your chain by deliberately being dense. The
questions are nonsensical and remind me of that old "Eliza" software that
would take your words and run you around in endless circles.

It doesn't matter. 12v is 12v.. But to answer your question,
I open the hood of the car, and attach the wires to the battery
while it's in the car. That way I can start the car to charge
the battery every once in a while.
But the power source of the radio has nothing whatsoever to do with
the antenna. I could place the battery anywhere and the operation would
be the same. The car is not part of the antenna. The *complete* antenna
is suspended between a couple of oak trees well over my head.
The antenna is decoupled from the feed line. And there are no
connections to ground. One could consider the negative power lead
as connecting to a "chassis", IE: the body of the car, but that is
a DC connection, not RF.
Moving the battery would make no difference whatsoever in the
performance of the antenna.

Hello again.

I agree. I'm sure that Marconi was bright enough to investigate new ideas. I
was at a social event with his widow and daughter a long time ago but there
wasn't
time to ask her about him.

Regards, Ian.

I guess all the people I talk to using that portable rig
are just a figment of my imagination?
And likewise here at the house where most of my systems are
ungrounded..
It's actually quite astounding.. I've worked about 29
zillion people using various ungrounded antenna systems that don't work.

How did I pull off such a feat? Did I scream real loud?
Did I hire R. Lee Ermey to scream for me? He's pretty good at it..
Maybe I built a big fire behind the radio, and sent smoke signals..
I suppose that could be a viable explanation, being as that land was
Indian Territory until a couple of years before Marconi made that
statement. :\
I don't own any war drums, so we would have to rule those out.. :|
Maybe I pass notes around the country on the backs of tarantulas..
They usually don't mind as long as I don't use a hat pin to attach
the notes to their backs.

<snip>

Nope. Not at all. I have quite a few contacts with a Heathkit HW-7 powered
with 8 "D" cells, a homebrew balanced tuner and open wire dipole. This was
use on board a sailboat.

Each the earth/chassis/counterpoise are the DC nett connection.

> Moving the battery would make no difference whatsoever in the
> performance of the antenna.

"Would" means that you are not sure.

If you want to be sure you can make the two experimments:

1. Take off the car battery and sit it on the stone bench, and/or

2. Instal the ammeters on the each wires to the battery while it's in the
car.

Would be nice to know the results.
Best Regards,

It contradicts to the known phenomenon that each charged body lost its
charge in a short time. AT EACH VOLTAGE.

So your claim is that it is sufficient to "have the chassis" and that
this chassis does not have to be connected to the earth?

What constitutes "the chassis"?
Do you have any minimum size for the chassis to be a chassis?

are caught with a mistake.
```

911. Ground

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-18 09:05:10 UTC
From: Szczepan Bialek <sz.bialek@wp.pl>
Message-ID: <4f8e83c6$0$1295$65785112@news.neostrada.pl>
Source record: 2428

". In electronic circuit theory, a "ground" is usually idealized as an infinite source or sink for charge, which can absorb an unlimited amount of current without changing its potential. Where a real ground connection has a significant resistance, the approximation of zero potential is no longer valid. Stray voltages or earth potential rise effects will occur, which may create noise in signals or if large enough will produce an electric shock hazard.
The use of the term ground (or earth) is so common in electrical and electronics applications that circuits in portable electronic devices such as cell phones and media players as well as circuits in vehicles such as ships, aircraft, and spacecraft may be spoken of as having a "ground" connection without any actual connection to the Earth. This is usually a large conductor attached to one side of the power supply (such as the "ground plane" on a printed circuit board) which serves as the common return path for current from many different components in the circuit." From: http://en.wikipedia.org/wiki/Ground_(electricity)

There is wrote that all of your transmitter have "a "ground" connection without any actual connection to the Earth."

Each transmitter needs " an infinite source or sink for charge".

The above you know.

But some of you do not know that where the voltage is there is the field electron emission. So the sink is necessary.

It must not be infinite. "a large conductor" absorb the electrons from the air. So its size must be adequate to the emission.

Nice Fun.

I know that it is not true.
A transmitter needs no infinite source or sink for charge because it
does not generate any DC current into the antenna.

Ok so we can finally rest the case and agree that a connection to
earth is not required for a transmitter, something you have claimed
all the time because Marconi wrote it.

No, "would" means just that. And I am sure.
>
> If you want to be sure you can make the two experimments:

I'm already sure. I've run more portable stations over the
years than you can imagine. With batteries in and out of the
cars, using various types of "complete" antennas, and also
using the vertical antennas on the vehicles.
Even if I use an antenna on the vehicle, which *would*
use the car body as part of the antenna, where I have
the battery or radio makes no measurable difference in antenna
performance.

How does one actually measure the voltage on the ends of an antenna?

Hello chaps. Let's not worry about Szczepan's misunderstanding of the word
"would".
I like the idea of the ammeters - I think I saw something similar in a
textbook I have from the 1920s or 1930s.

Best wishes to all, Ian.

Good afternoon ladies and gentlemen.

Do any of you teach students hoping to gain an amateur radio licence?
Some of Szczepan's postings would be useful for amusing those students and
informing them how it is definitely not done.

Hope you all have a fine Wednesday,
Ian.

Hello again folks.

{I am concerned about Szczepan. He's cut-and-pasting from Wikipedia. Is he
safe with a sharp pair of scissors?}
I'm not sure whether to suggest that he also look at "chassis" and "common
point".
More seriously, I guess this is an example of a common word, "ground",
having more than one technical meaning and this bringing confusion to the
lay person.

I really wish that Szczepan would get hold of a training manual for the
amateur radio licence exams. The usual diagrams would enlighten him.

Kindest regards from a wet UK, Ian.

Ah - so there still are some articles in Wikipedia that lack technical
accuracy. The quote above demonstrates poor use of the word "ground" and
that's caused Szczepan to misunderstand.

Regards, Ian.

It is true because it generate the oscillatory flow of electrons into the
antenna.
In such case the DC ammeter idicates the current.
>

Marconi wrote:
""By "connected to earth" I do not necessarily mean an ordinary metallic
connection as used for ordinary wire telegraphs.
The earth wire may have a condenser in series with it, or it may be
connected to what is really equivalent, a capacity area placed close to the
surface
of the ground (Fig. 4)."

" a capacity area placed close to the surface of the ground" = " large conductor "

The case will be ready to rest if you admit that Marconi was right in his Nobel lecture.

Nope.

> The above you know.

Meaningless babble.

> It must not be infinite. "a large conductor" absorb the electrons from the

More meaningless babble.

Antennas do not have a chassis.

In the days of wired electronics, the chassis was the metal box the equipment was built in and used as a common return, i.e. what is called ground but has no relationship to the Earth. By convention it was mearly the common connection point for the most negative voltage.

In todays world of circuit boards, there is often no chassis.

Most portable equipment these days is a circuit board in a plastic box.

No chassis.

No ground, as in to the Earth, connection.

It is a pity that you don't have a transmitter, or otherwise it would
be easy for you to see for yourself that you are talking nonsense!

There is no DC current from a transmitter into the antenna.

I believe in each your word. But I simply do not know where in your
equipment the "large conductor" is.
Probably it is the coax: "Many conventional coaxial cables use braided
copper wire forming the shield".

I also belive in each Tesla's word. He discovered that in his secondary coil
is the oscillatory electron flow from the earth into the air.
Why is it impossible?
S*

In your statements, you never specify what a "large conductor" is.
Today, transmitters are often very small and still they work OK without
any earth connection.
How large should a "large conductor" be?

> Probably it is the coax: "Many conventional coaxial cables use braided
> copper wire forming the shield".

The transmitted signal flows only along the inside of the shield of the
coax. The outside is supposed to carry no signal. If it does, there is
a problem with the antenna system.

> I also belive in each Tesla's word. He discovered that in his secondary coil

> S*

We do not operate our transmitters in the region where electrons start
flowing into the air, because we do not like arcing. Tesla did, but he
was in a different business.

> Why is it impossible?

Because RF EM waves are not made up of electrons. The particles that
are flowing in an RF EM wave are photons. RF waves travel at the speed
of light. Electrons cannot travel at the speed of light. If Tesla
actually believed that an RF wave consists of electron flow, he was
simply ignorant of quantum electrodynamics. That may be the reason why
he failed to transfer large amounts of power through the air in an
efficient manner.

Electron waves travel. Electrons have different speeds like the all gases.

He wrote that for this you must use the higher frequency than was possible
in his time.
Now all transfer large amounts of power through the air in an efficient
manner.
Light is an example. But now we have the free electron laser.

> In your statements, you never specify what a "large conductor" is.

Here you are:
"". In electronic circuit theory, a "ground" is usually idealized as an
infinite source or sink for charge, which can absorb an unlimited amount of
current without changing its potential. Where a real ground connection has a
significant resistance, the approximation of zero potential is no longer
valid. Stray voltages or earth potential rise effects will occur, which may
create noise in signals or if large enough will produce an electric shock
hazard.
The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit." From:
http://en.wikipedia.org/wiki/Ground_(electricity)

> Today, transmitters are often very small and still they work OK without
> any earth connection.
> How large should a "large conductor" be?

Adequate to electron emission.
>
>> Probably it is the coax: "Many conventional coaxial cables use braided

Electron do not start.
Electrons are flowing into the air (and vacuum) at each voltage.
The thin wire is the best "cold cathode".
What are your antennas made of?

Transmitters do not emit electrons. They emit electromagnetic waves.
You only see electric current in the feed to the antenna, not externally.
When the antenna is not driven relative to earth, this is not causing
current into the earth, and so no connection to earth is required.

But in my cellphone, the coax feeding the antenna is maybe only 1cm
long, or even shorter. How can you call it a "large conductor"?

What current do you measure in a wire connected to your 12v car
battery, and hanging freely into the air?
This is the current caused by your electrons flowing into the air.

> Transmitters do not emit electrons.

"Negative corona take place at each voltage:
"A corona is a process by which a current, perhaps sustained, develops
between two high-potential electrodes in a neutral fluid, usually air, by
ionising that fluid so as to create a plasma around one electrode, and by
using the ions generated in plasma-processes as the charge carriers to the
other electrode.
Corona discharge usually involves two asymmetric electrodes, one highly
curved (such as the tip of a needle, or a narrow wire) and one of low
curvature (such as a plate, or the ground). The high curvature ensures a
high potential gradient around one electrode, for the generation of a
plasma.

Coronas may be positive, or negative. This is determined by the polarity of
the voltage on the highly-curved electrode. If the curved electrode is
positive with respect to the flat electrode we say we have a positive
corona, if negative we say we have a negative corona. The physics of
positive and negative coronas are strikingly different. This asymmetry is a
result of the great difference in mass between electrons and positively
charged ions, and so only the electron having the ability to undergo a
significant degree of ionising inelastic collision at common temperatures
and pressures.

An important reason for considering coronas is the production of ozone
around conductors undergoing corona processes. A negative corona generates
much more ozone than the corresponding positive corona. " From:
http://www.wordiq.com/definition/Corona_discharge

"the tip of a needle, or a narrow wire" is a source of the "cathode rays".
They were identyfied in 1895."

> They emit electromagnetic waves.

""the tip of a needle, or a narrow wire" is a source of the electrons.

For 12 V it should be the nanometers.

Take a rest.

No, it does not.

Corona only occurs with sufficiently high voltages.

The voltages on most antennas is no where high enough to cause corona.

> "A corona is a process by which a current, perhaps sustained, develops
> between two high-potential electrodes

There you have it: "two high-potential electrodes".

<snip>

>> But in my cellphone, the coax feeding the antenna is maybe only 1cm
>> long, or even shorter. How can you call it a "large conductor"?
>
> "Large enough."

There is no coax in my cellphone, my 2M handheld, or my aviation handheld.

The cases of all of them are plastic and there is no "large conductor" nor
is there any "ground plane".

Yet they all work.

You are a babbling idiot.

<snip>

> ""the tip of a needle, or a narrow wire" is a source of the electrons.
>
> For 12 V it should be the nanometers.

For 12V there is no corona as the voltage is too low to initiate a corona
no matter how small a tip you put on the wire.

He was wrong on several counts.

He also died well before Einstein and others came along and got it right.

That's the problem with obsessing over stuff that was written 150 years
ago, a lot of it was found to be wrong.

Lorenz was wrong about the composition of light.

Marconi was wrong about antennas having to be grounded to work.

> In today's words: "Light is the oscillatory flow of electrons".

Nope, in todays words light is electromagnetic radiation that is visible
to the human eye.

> Light and radio waves are the same.

This is one of the very few true statements you have ever made.

> Are the radio waves the oscillatory flow of electrons?

No.

The phrase "oscillatory flow of electrons" is gibberish.

Well, lessee... gain would be the same as any dipole, i.e. about 1.76dBi
not considering resistive losses because you did not specify a conductor
size. Resonant frequency would be ~.372 Hz. This does not include the
"capacitive hats" of the earth and moon.

> 73, Ian.

Where would "ground" be?

Hello Ian.

I had wondered if that might be the case but I tended more towards
cut-and-paste by someone who find Wikipedia pages.

73, Ian.

John, "ground" is so "last century" along with "dial-up" and "Cathode Ray
Tube in my television".
Forget "ground". Say "planet" instead. Is that better?

Oh - sorry about missing that, John.
How about going for any two planets which form a straight line? This is surely better than relying on just one planet which might develop an eccentric orbit (which we could name the "S****pan orbit").
Besides which, someone, sometime in the future, might want to hang a long wire between the planets (but how much would the feeder cost).

Okay - if you prefer only on planet then I suggest Saturn (let's talk halo aerials) or Jupiter with its jolly red spot (well, you try getting a tube of cream THAT big).

I suppose the best evidence of using ground / planet is moonbounce - uses the ground / planet without an aerial at that end of the path.

73, Ian.

He is an idiot that cuts and pastes from web pages.

Most of the pages he uses are historical in nature.

I have no clue what motivates the little idiot to be such an idiot, but
I suspect brain chemical problems.

Okay. But how many planets have bounced from their "ground" a signal?
Does that mean that they are not really there, just an artifact of
telescopes?

Hello again. He reminds me of someone who is elderly and thinks that all textbooks are the same ... so reads the ones from the 1930s and 1940s. This fits in with the "Marconi was right" persuasion for, surely, Marconi was synonymous with radio (though those of us who know something about Marconi know that he developed radio from existing ideas).
I have had to help a few such people with "new" technology such as digital television, digital radio and digital cameras. They find it hard to accept that things have changed since they were young.
I'd like to know if Marconi saw his aerial as a device in its own right (i.e. "here is a transmitter" and "here is an aerial") or simply as the part of the transmitter that happened to be better at "projecting" a signal than a piece of wire dangling from the end of a transmitter.

73, Ian.

Marconi certainly concidered an antenna to be a separate piece of equipment
and the word "antenna" comes from his use of the Italian word antenna, meaning
pole, to describe them.

It is becaue of his prominence the word spread to the general public.

Since light is nothing more than very, very high frequency RF, all of them.

> Electron waves travel.

No doubt, and please give an example of an electron wave. One more time. It is impossible for electrons to travel at the speed of light. But RF EM waves travel at the speed of light. Therefore, it is impossible for RF waves to consist of electrons. Electrons act as a bucket brigade for "buckets" of photons.

> And what about the "displacement current?

If Maxwell had known about photons, he would never have invented
displacement current.

Assume we have an ideal transmission line terminated in an ideal
capacitor with two plates. It's easy to prove that the displacement
current flowing from one plate back up the transmission line, through
the source, back down the transmission line onto the other capacitor
plate has to be traveling much faster than the speed of light. Does
that give anyone pause to question the very existence of "displacement
current" in reality?

Back when physicists and engineers were ignorant of the existence of
photons, that was the best they could do to explain electromagnetic
fields surrounding free electrons being energized by AC signals.
Nowadays, we know that at RF, the electrons oscillate virtually in
place and it is the photons that are responsible for energy transfer
(flow).

While I do not disagree with what you said, note the 's' in "Electron waves".

A particle may have some wave properties but that does not make it a wave.

Yup. In 1950, when I was 7, I acquired the Compton's Pictured Encyclopedia,
1930 edition. I was an avid reader and I loved those books.

However, it didn't take me long to start finding errors -- or perhaps
"inconsistencies," to be kind -- with more recent thinking.

Nominally, those books were only 21 years old -- like from 1991 to today.
But I presume many of the articles dated from prior editions, some maybe
already decades old by 1930.

The main problem is not in the articles, but in the strange way
you interpret them. The article about ground explains what is
wrong with your reasoning, but you still don't get it.

time. It is impossible for electrons to travel at the speed of light.
But RF EM waves travel at the speed of light. Therefore, it is
impossible for RF waves to consist of electrons. Electrons act as a
bucket brigade for "buckets" of photons.

In the space is the rare plasma. There are the acoustic waves and the
electron waves.

According to Wikipedia, Stokes Drift applies to wave motion in fluid
dynamics. The article predominantly mentions water. Article makes no mention
of its application to radio signals.

speeds.

Electron waves travel in the Dirac electron sea with the speed of light.
Like the sound waves in the air.

In space are ions and electrons (rare plasma).
Electron waves travel from the Sun about 8 minute and the acoustic (ion
waves) a few days.

In vacuum is rare plasma (ions and electrons). Plasma is a conductor.
The electrons are free to move.

If the propagation of electromagnetic waves would be dependent on
residual electrons present in the imperfect vacuum (like in space),
there would be a tendency for propagation to become worse when the vacuum
would be more and more perfect. There is no such effect ever observed.

That's because there isn't any.

It only applys to fluid dynamics, as in water and gases, not free space.

Once again the babbling little idiot does a web search for a phrase or
word like "wave" and is too blindinly stupid to understand that the word
can have more than one meaning.

I am a little surprised that he hasn't posted something about WAVE actions
in WWII.

>
>> What is the source of the heat in microwave oven?
>
> Resistive loss.

No, I don't think so. A microwave works by agitating the water molecules
because they are dipoles that twist around in the electromagnetic field.
As an increased level of agitation is equivalent to higher temperature,
this immediately heats the water independent of resistive losses.
(which of cause will be a factor when attempting to heat stuff that has
no bipolar molecules and/or when using a resistive container to bake
rather than merely heat something)

I think I see the problem. I phoned my cousin, our Ambassador to Elbonia,
and asked him about the translation of "babbling idiot." He says it's taken
as a compliment. Only the top few of Great Elbonian Thinkers are worthy of
such high regard.

Actually I meant to say dielectric loss; you are correct.

Try to resist the urge to "check back". The group will become accustomed to your absence, eventually, and carry on as it should. You're visitation might lead to another undesirable experience for you and then the group might have another painful withdrawal when you leave again. Try to be considerate.

Too bad your news client doesn't have a useful filter.

Mikek - THANKS for the link to Rescue Tape! That looks to be exactly what I need to protect the fiberglass base insulator, which is actually still in pretty good shape. I replaced the short section of braid between the matching box and the radial spokes with a nice bit of tinned braid strap. Everything came apart pretty easy and was cleaned with a green ScotchBrite pad, and this time I used plenty of Penetrox at the joints and on the threads. Excellent so far.

The antenna is mounted atop a ten-foot + length of hurricane fence rail which is mounted to a cheap three-foot RS galvanized tripod. The tripod

is bolted to a T-shaped base fabricated from 1 X 8 pine such that the whole thing can be tilted down by removal of a stainless wing nut that holds down the rear tripod leg. The base is fixed to the ground with three really big tent stakes; a set of three dacron guys completes the simple installation.

Once again, many thanks to y'all for the good ideas!

If you were happy with it's performance when it was new - you should have bought a new one when the storm damaged it - before MFJ got their grubby paws on the company and cheapened it up.

It you was good at fabrication - you probably could have made the replacement parts yourself.
And how did it work great for your mom if there was parts missing.

This whole post is a misnomer.

Throw it away, buy a new one, put it up according to the manufacturers specifications and hope that it works as well as the one you bought years ago.

My theory is sentimental value is always 100 cents on the dollar.
Real world tells me that unless you put up the same exact antenna on the same exact location and had the same exact propagation - nothing ever works the same 100% of the time...

Who "has proven this to be inaccurate."?

Before Cate were Ampere, Faraday, L. Lorenz, Tesla and Dirac.
>
> You will ignore, or discount with babble, this statement as you do with

Your statement should be supported with names of scientists.

Things are changing.
From beggining to IWW the light and radio waves were the "electric waves".
After IWW they becomes the "EM waves".
In XXI century they are "electron waves".
http://en.wikipedia.org/wiki/Waves_in_plasmas
Where the oscillating species are electrons.

Continuous waves are opposite to damped waves.
Continuous with the changde amplitudes are AM (amplitude modulation) or FM.

Wind is like the electron beam. They travel with the "wind' speed.
The sound and electron waves like the oscillating species (electrons or
molecules). They travel with the wave speed.

Up to now we see distant stars. The plasma is produced by stars. So we are
not in perfect vacuum.
My be that such is behind the last star.

1022. Autoelectronic emission

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-21 07:24:03 UTC
From: Szczepan Bialek <sz.bialek@wp.pl>
Message-ID: <4f926093$0$1208$65785112@news.neostrada.pl>
Source record: 2139

Most of you wrote that your antennas work below the voltage necessary to start the electron emission.

But in reality the emission take place at all voltages.

" Attempts to understand autoelectronic emission included plotting experimental current-voltage (i - V) data in different ways, to look for a straight-line relationship. Current increased with voltage more rapidly than linearly, but plots of type (log(i) vs. V) were not straight"

"A breakthrough came when Lauritsen[13] (and Oppenheimer independently[14]) found that plots of type (log(i) vs. 1/V) yielded good straight lines. This result, published by Millikan and Lauritsen[13] in early 1928, was known to Fowler and Nordheim.
Oppenheimer had predicted[14] that the field-induced tunneling of electrons from atoms (the effect now called field ionization) would have this i(V) dependence, had found this dependence in the published experimental field emission results of Millikan and Eyring,[10] and proposed that CFE was due to field-induced tunneling of electrons from atomic-like orbitals in surface metal atoms. From: http://en.wikipedia.org/wiki/Field_electron_emission

Electrons escape from each charged body. Your antennas emit electrons and for this reason they need the sink of electrons (the earth/chassis/ counterpoise).

Of course not.
Not only is this effect too small to be measured at voltages common
on a transmitter antenna, the voltage is also AC so these effects will
cancel out along the cycle of the AC wave. The net result will be zero.
There can only be a net current when there is a (large) DC voltage on
the charged body, which is not the case on a transmitter antenna.

Great theory. If antennas emitted electrons, and electrons have mass,
we could then build a rotating antenna powered by the electron
belching reaction mass. Put the antenna on a hub, and watch the
electron emissions turn the antenna as they fly off the antenna at
ummm... the speed of light. A few hundred watts of power should be
more than enough to move the antenna around. Yeah, great physics you
have there.

Hint: How fast do electrons travel in a wire?
No, it's not the speed of light. It's called electron drift velocity.
<http://en.wikipedia.org/wiki/Drift_velocity>
<http://www.jensign.com/JavaScience/www/cuwire/cuwire.html>
For the above example, it takes about 12 hours for an electron to
travel 1 meter in a copper wire. Not exactly at RF speeds.

Keep trying. Eventually, you'll get something correct.

That's funny.
I would improve for clarity by putting spaces between

Write in one cell: =(- A1^2 + 8) .... (result xxx(censored)
Write in another cell: =(8 - A1^2).............(result x(censored))

The result is same a yours, despite the spaces.
You may also enter negative numbers in A1 and also
decimal numbers, everytime a surprise.

Another Microsoft blunder?

The "oscillating species" can be electrons (e.g. free electrons in a
wire) in which case the wave energy is carried by photons. The
"plasma" of an outer space vacuum is NOT made up of electrons but of
dark matter exotic particles through which photons can travel. Give up
on the silly electron theory, replace it with a dark matter theory,
and there may be more than a grain of truth in what you say.

No. "Once liberated, electrons are strongly repelled by the high electric
field near the electrode during negative voltage peaks from the oscillating
HV output "

> There can only be a net current when there is a (large) DC voltage on
> the charged body, which is not the case on a transmitter antenna.

In a transmitter antenna is the "oscillatory flow of electrons" with the net
current from the earth into air.
S*

No. Excel's parser can't always tell whether you want to negate A1
before squaring or not. Don't be lazy; group with parentheses when in doubt.

-(A1^2) + 8
works exactly the same as
8 - (A1^2)

I see you didn't bother to include the part about it being dependant on
the work function, which means there is a minimum energy required.

Or more likely you just don't understand this anymore than you understand
anything else.

> Electrons escape from each charged body. Your antennas emit electrons and

1042. Solarcon Imax 2000 antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-21 18:12:52 UTC
From: Boomer <unavailable@nothere.com>
Message-ID: <cMCkr.162034$s82.143822@newsfe10.iad>
Source record: 2159

I just installed one of these and did a lot of experimentation with the tuning rings. This is a truly great low cost antenna for the higher bands. I use it on 10, 12, and 15 meters. My worst swr is 1.45 to 1 on 15 meters.

The bad news is that the owners manuals tells you to cut a foot off the top whip to tune this for 28.4 mhz. This would be a very bad move. I tried this by installing a whip that was already a foot shorter. It could be tuned for 28.4 but not for the other bands.

This antenna can be tuned for a 1.0 to 1 match on 28.4 with just the rings. I settled on a compromise that gave me a 1.2 to 1 match on 28.4, a 1.3 to 1 match on 24.950 and 1.45 to 1 match on 21.35 mhz.

Do not install the ground plane kit. This narrows the bandwidth to be unusable for hams.

The price for this antenna rated at 2000 watts is about 110 bucks shipped. Hard to beat this performer. I only use 600 watts on these high bands. I use 1500 on the lower bands where you really need it.

And no I have no relationship with solarcon other than being a happy buyer. If anyone is interested, my rings wound up beings set at 4 turns down from the top most position possible.

Michael

The blunder is not understanding operator precedence in Excel.
http://office.microsoft.com/en-us/excel-help/calculation-operators-and-precedence-HP010078886.aspx

Unary operators are before exponentiation.

Using more parentheses generally helps.

```
-A1^2 is interpreted as (-A1)^2 not -(A1^2)
```

Please let me know how far you can communicate using air molecules.
There is a momentum transfer when moving air, but it dissipates rather
quickly. Comparing electron dynamics with pneumatics just doesn't
work.[1]

>The same is with the electron waves speed and the electron beam (drift)
>speed.

Same as what? There is no such thing as an electron wave. There are
electron beams, and radio waves, with very little overlap.

If think that electrons fly off the ends of an antenna, there should
be a way to directly detect those electrons. For example, a CRT has a
phosphor screen that lights up when hit by electrons from the electron

gun. If your mythical electrons are really there, you should also be able to place a phosphor screen near a transmitting antenna, and have it light up.

Also, if your electrons are leaving the antenna, and flying off into the ether, there should be a rather large positive charge left on the antenna. If you then claim that the transmitter is replacing the electrons as fast as they are radiated, then the positive charge should reside in the transmitter. If you then claim that the local electric utility is supplying electrons to the transmitter, then the utility generating station must have a huge positive charge.

> Keep trying. Eventually, you'll get something correct.
>S*

You're not trying hard enough. Open book, insert face, absorb everything, and verify what you've learned using real world examples and numerical calculations. If your theory of the moment can't be reduced to real (i.e. non-quantum) physics, with real calculations, and real experimental verification, it's probably wrong.

[1] Maybe this will help. It's not a perfect analogy, but it's close enough. Find a billiard table and line up about 10 balls in a line and as close together as possible. Use another ball to hit one end of the line, and time how long it takes between the first impact, and when the ball at the end starts to move. Now, cover the same distance with just the cue ball, and without the line of billiard balls. Note how it take MUCH longer for just the cue ball to travel the same distance. The line of billiard balls represents the atoms in a conductor. You'll get electron transport at almost the speed of light in such a situation. The cue ball alone represents the electron drift in the same conductor. If the cue ball could be made to travel at the same speed as it did through the line of billard balls, the felt on the billiard table would probably show a deep burn mark.

1046. Icom PCR1000 antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-21 22:23:11 UTC
From: Jeff Liebermann <jeffl@cruzio.com>
Message-ID: <3vb6p7p00kcbi2cm20ssd5ldbukq7h4fnt@4ax.com>
Source record: 2163

For some irrational reason, that probably defies logical
justification, I've decided to setup my PCR1000 receiver as an
internet accessible receiver. There are about 7 programs available to
do this, so I don't expect software to be a problem. The receiver
will eventually be moved to a mountain top repeater site, which
unfortunately does not have much room for an antenna. The receiver
will tune from 0.1 to 1300Mhz. I don't wanna deal with an antenna
tuners or switches.

Is there an antenna or combination of antennas that are suitable for
such a wide tuning range and that is small enough to fit in a limited
rooftop area?

I was thinking of a monstrous vertical biconical dipole for HF, a
diplexer, and a discone for VHF/UHF/etc. For Field Day, I once made a
biconical out of two trash can lids, with holes for the wires around
the perimeter. It worked amazingly well but I never bothered to make
measurements.
<http://en.wikipedia.org/wiki/Biconical_antenna>

Can anyone suggest something better, smaller, less ugly, or more
practical?

One thing not to forget is there are relatively inexpensive duplexers/triplexers/etc. from the likes of Comet and others. Or roll your own.

I know that doesn't help much on the low end of things but means a couple discones on the mid and upper will do well.

And yes there will be some small to medium gaps because of the device.

If it's always receiving and you can make an amplifier with high input impedance throughout the frequency range, then you could use a short dipole 'doublet' - drawing insignificant current from the antenna would make its very low radiation resistance less of a concern. Its directivity gain would be almost constant because its radiation pattern comes from its (fixed) axial symmetry, but a wavelength^2 factor would apply to its effective aperture area. It probably wouldn't be easy to design a single high-input-Z amplifier over that frequency range, but there might be scope for dividing the range and combining the _outputs_ of several amplifiers, each fed by their own doublet.

Would you need any kind of 'monstrous' antenna if the requirement was always receiving? I could see that you might want something large to get the

radiation resistance up if you were transmitting from it, but for receiving a high-Z amplifier becomes easier at lower frequencies. I vaguely recall that some of the companies that have offered professional 'radiomonitoring' (i.e. evesdropping) equipment, such as R&S, have used combinations of different types of element for different parts of the wide frequency band, but never anything monstrous.

I like to make my own diplexer/triplexer boxes. In this case, only a
diplexer is needed. The Radio Shack discone antenna will (allegedly)
work from 30-1300MHz.
<http://www.radioshack.com/graphics/uc/rsk/Support/ProductManuals/2000043_PM_EN.pdf>
Below 30MHz is the real problem. Also, none of the commercial
diplexers I could find had a 30MHz cutoff frequency. Looks like I get
to build something.

>I know that doesn't help much on the low end of things but means a
>couple discones on the mid and upper will do well.

I've compared the performance of discones and biconical antennas.
Biconicals are better because the radiation pattern is towards the
horizon, instead of towards the sky. It also has about 1-2dB more
gain. However, I'm not in the mood for building yet another
mechanical marvel, and will probably use the discone.

>And yes there will be some small to medium gaps because of the device.

I can probably ignore the TV bands (54 to 700MHz) but I want most
everything else.

Thanks much.

Good idea. I've done that before with a long wire (about 200ft)
feeding a 3:1 turns ratio torrid xformer. It was a bit lossy at low
frequencies, but that doesn't matter because the atmospheric noise
level is so high, that everything is buried under the noise anyway.

>then you could use a short dipole
>'doublet' - drawing insignificant current from the antenna would make its
>very low radiation resistance less of a concern.

A doublet may not work at a commercial mountain top site. Doublets
require twinlead or ladder line down to the radio. The feed line will
need to either go through about 3 meters of pipe, or through a coax
bulkhead feedthrough. I could probably install the balun before it
enters the pipe or building, but that might not be practical.

>Its directivity gain would
>be almost constant because its radiation pattern comes from its (fixed)
>axial symmetry, but a wavelength^2 factor would apply to its effective

I don't have much in the way of expectations in the way of antenna
gain. If it receives anything, I'm happy.

>It probably wouldn't be easy to design a single high-input-Z
>amplifier over that frequency range, but there might be scope for dividing
>the range and combining the _outputs_ of several amplifiers, each fed by
>their own doublet.

Do I really need an amplifier just to do an impedance downconversion?
I would think a 3:1 xformer would be adequate.

Actually, it's quite easy to build a high input impedance RF
amplifier. I've done it many times. A source follower will do the
trick. So will a grounded gate amplifier. Better yet, a dual gate
MOSFET amplifier or some kind of cascode amplifier derangement. All
of them can be configured for a high input impedance and 50 ohms
output.

However, performance may not be so wonderful. It's a tradeoff between
gain, noise figure, and bandwidth. There's no easy way to make an
amplifier that is ideal for all three. Pick any two. Actually, it's

worse because blocking, overload, and dynamic range are also a factor. Putting a broadband amplifier on a mountain top full of broadcast stations and commercial radios is not a great idea. I'll probably end up with a transformer followed by an attenuator.

>Would you need any kind of 'monstrous' antenna if the requirement was always
>receiving?

Well, no... but bigger does tend to be better. I could probably use a base loaded whip, tolerate the mismatch losses, and live with the general loss of gain at the low end of HF. The site has an 80ft tower, where I think (not sure) I can install two outriggers, egg insulators, and build some kind of vertical wire antenna. Various configurations are possible, but the monstrosity I was considering is an HF biconical.
<http://www.google.com/patents?id=LJ9pAAAAEBAJ>
What I like about it is that it's 75 ohms over at least one octave of bandwidth. However, as each element approaches 1/2 wave at some frequencies, the impedance goes sky high. The trick is to put those frequencies in areas where I don't care to listen.

I could also fit a "fan" type dipole antenna or a wire simulation of a "bow-tie" antenna. However, what I was hoping for was some manner of fairly short antenna (about 3-6 meters), with a fixed LC network that yields a fair approximation of 50 ohms. 2-30MHz, without tuning. I've been playing with such a matching network in 4NEC2, but getting nowhere. Surely, such a thing exists.

>I could see that you might want something large to get the
>radiation resistance up if you were transmitting from it, but for receiving
>a high-Z amplifier becomes easier at lower frequencies.

True, but for there reasons I previously mumbled, I don't think an RF amp on an RF polluted mountain top is a great idea. Besides, additional RF gain at the low end of the HF spectrum is useless because of the high atmospheric noise levels. All the gain does is lower the receiver dynamic range.

>I vaguely recall
>that some of the companies that have offered professional 'radiomonitoring'
>(i.e. evesdropping) equipment, such as R&S, have used combinations of
>different types of element for different parts of the wide frequency band,
>but never anything monstrous.

Yes, but I suspect they also used antenna tuners to deal with the mismatch. I could do the same thing, but don't have an easy way to control the antenna tuner, especially since the receiver doesn't have the concept of "bands".

Thanks much.

Thats a good rule of thumb. However, this is a receive only antenna,
which does not need to be perfectly matched and can be fairly
inefficient and low gain. Even so, I don't think the radiation
efficiency is going to be that horrible. They're mostly due to
conduction losses (at HF) and dielectric loss (at UHF). For the high
currents required for transmitting, these losses are fairly large for
a short broadband antenna. However, in a high impedance receive only
antenna, the conductivity loses are a much smaller part of the antenna
impedance than in the transmit antenna.

It's much the same in the discone. The antenna VSWR averages about
3:1 over about 6 octaves of frequency. With such a high VSWR, it's
not a suitable transmit antenna. However, for receive, it works
tolerably well.

Well, he thinks that this is what is happening and therefore he
believes that any transmitter should always be grounded so that the
earth can supply the missing electrons and prevent the transmitter
from being charged more and more.

However, we all know this doesn't happen. He himself has no way to
verify it because he does not have a transmitter (or he is not bright
enough to realize that maybe he has one in his pocket).

So he keeps insisting that the transmitter must be grounded or problems
would occur because of the electron emission. When everyone agrees that
these problems do not occur, he does not realize that maybe the electron
emission is not there at the voltages involved, and he was wrong after all.

Ampere, Faraday, Stokes, Lorenz, Tesla and Dirac analyzed and explained
everythig.

"Maybe this will help":
1825 - Ampere publishes his collected results on magnetism. His expression
for the magnetic field produced by a small segment of current is different
from that which follows naturally from the Biot-Savart law by an additive
term which integrates to zero around closed circuit. It is unfortunate that
electrodynamics and relativity decide in favor of Biot and Savart rather
than for the much more sophisticated Ampere, whose memoir contains both
mathematical analysis and experimentation, artfully blended together. In
this memoir are given some special instances of the result we now call
Stokes theorem or as we usually write it. Maxwell describes this work as
``one of the most brilliant achievements in science. The whole, theory and
experiment, seems as if it had leaped, full-grown and full-armed, from the
brain of the `Newton of electricity'. It is perfect in form and unassailable
in accuracy; and it is summed up in a formula from which all the phenomena
may be deduced, and which must always remain the cardinal formula of
electrodynamics.'' From:
http://www.electricityforum.com/a-timeline-of-history-of-electricity.html

"a small segment of current" = electron.

"the Biot-Savart law" = hydraulic analogy.

Teaching and science are the two different things. In teaching is the
hydraulic analogy in science are electrons.

"It is unfortunate that electrodynamics and relativity decide in favor of
Biot and Savart rather than for the much more sophisticated Ampere".

Maybe in 1900, but not today.
This is because it was found that an antenna does not emit electrons.

Oscillating (vibrating) molecules is a measure of heat energy. With
that explanation, it would be necessary for antennas to be hot in
order to radiate. Try again please.

>But no smaller species than the electrons.

Other than positive electrons, there is only one type of electron.

>Tunnig fork transfer its energy to air molecules, air molecules to electrons

>
>Cathode rays were idenified in 1895.

My antennas do not emit cathode rays. If they did, my neighborhood
would be bombarded with electrons, potentially destroying everything
it its path.

Please produce a reproducible test, that will demonstrate that charged
electrons are being emitted by an antenna. Your Nobel prize awaits
you.

>> Also, if your electrons are leaving the antenna, and flying off into
>> the ether, there should be a rather large positive charge left on the
>> antenna.
>
>You call it "static".

Static electricity? The word "static" means not moving. With static
electricity, surplus electrons (or lack of electrons) are accumulated
on an object, giving it a negative (or positive) charge. The point is
that they are not moving, just sitting there. Ever try to stop an RF
signal? You can't. You can slow it down through various materials,
but you can't stop it. RF and static are not the same. Try again.

> >If you then claim that the transmitter is replacing the

In case you haven't noticed, power lines are a balance pair. For 3
phase, they are also balanced at 120 degrees apart. The ground
connection is strictly for safety and is not required for proper
operation. It's there for safety, in the event you decide to prove
your theory by discharging the mythical positive accumulated charge to
ground through your body.

>It could not be wrong because such Giants as Ampere, Faraday, Stokes,
>Lorenz, Tesla and Dirac were "using real world examples and numerical
>calculations."

Pick one sample calculation that demonstrates that electrons are being
emitted by transmitting antennas. There are plenty of tests that will
detect electrons. Pick one.

>Ampere, Faraday, Stokes, Lorenz, Tesla and Dirac analyzed and explained
>everythig.

True, but you haven't explained anything.

>http://www.electricityforum.com/a-timeline-of-history-of-electricity.html

Thank you for the history refresher. Unfortunately, I didn't see
anyone claiming that antennas emit electrons. Could you be a little
more specific.

>"a small segment of current" = electron.

Segment? So, if I take a conductor, and cut out a segment, I can walk
away with several amps of current contained in that segment? Amazing.

>"the Biot-Savart law" = hydraulic analogy.

<http://en.wikipedia.org/wiki/Biot-Savart law>
I fail to see any mention of hydraulics in the above article. Also,
your analogy was pneumatic, not hydraulic.

>Teaching and science are the two different things. In teaching is the
>hydraulic analogy in science are electrons.

I'm sure the teachers in this group will be thrilled to know that what
they're teaching is not science.

>"It is unfortunate that electrodynamics and relativity decide in favor of
>Biot and Savart rather than for the much more sophisticated Ampere".

If there's a conflict, simple explanations tend to prevail.
<http://en.wikipedia.org/wiki/Occam's_razor>
Sophistication is for science fiction.

Static electricity or radio static noise? Static electricity should
not be a problem as the PCR1000 probably has a 100K resistor across
the antenna connector. This is standard on most radios. If not, I
can easily add one to bleed off any excess charge.

At VHF frequencies, any generated radio static should not be a
problem. The building is high enough that it might end up inside a
thunder cloud, where precipitation static might cause trouble.
Besides, there's not enough dielectric material on the discone to
build up much of a charge. If the humidity is low enough and the wind
speed high enough to create arcing, I'll have much bigger problems
than to deal with than a little static noise.

However, there may be another problem. We try to use grounded and low
impedance antennas on mountaintop sites in order to reduce induced
currents from nearby lightning hits. Both my proposed antennas are
ungrounded and/or fairly high impedance. Oh-oh.

Totally wrong. The power lines and receiver antennas must have ground
connection.
"The wire antennas used with crystal receivers are monopole antennas which
develop their output voltage with respect to ground. They require a return
circuit connected to ground (earth) so that the current from the antenna,
after passing through the receiver, can flow into the ground. The ground
wire is attached to a radiator, a water pipe, or a metal stake driven into
the ground.[4"

Do you think that monopole antennas are the only existing antennas?
It seems you do.

However, that is not true. A dipole antenna does not need a ground
connection as the output voltage is not with respect to ground, but
between the two terminals.

Couldn't stay away! I knew when I departed that I'd be back eventually -- but I didn't realize how quickly. I should have known. My only interest now is in antennas. I just moved into a senior's residence where outside antennas or anything on the roof are out of the question -- at least that's what they think. I will be QRP using a Yaesu FT-817ND.

Over the years, before assorted medical problems lay me low, I helped a lot of hams who thought they'd have to forgo the hobby (due to antenna restrictions) get on the air. Now it's my turn to help myself!!!

I tried working using an indoor antenna but with all the metal in the frame of the building and around the windows it appears that this option is out of the question. Even a wire loop taped to the window couldn't get WWV when a chum of mine was getting it 20 over 9! I tried dropping a line outside the window to near the ground, but it receives little if anything -- probably due to the capacity between the antenna and the building. I did find that if I strung the wire out perpendicular to the building it worked beautifully.

I have now drilled a small hole (about 1/4 inch) through the window frame and plan to string some fairly invisible or very low profile wire out from the window and over a nearby tree with the end hanging down through the tree. Using this with an MFJ-1625 tuner I should be able to get out well. The tuner has a separate inductor which allows me to tune the counterpoise (which I can run along the wall in my suite), and combining this with low power and some RF Chokes on the power supply line I should be able to operate. It's difficult to quit after over 50 plus years of ham radio.

In any event, once I get on the air I can consider other antenna alternatives, but the immediate need is to get a signal out and myself back on the air.

This afternoon I'm going to a surplus warehouse searching for some suitable wire to string. I have a couple of questions re my setup that I've never had to deal with before, so that will be my next posting on this group.

As for my problem re trolling I guess I'll have to use blocking techniques which I didn't want to have to employ in fear of missing some good information. In any event, here I am again and I'm happy again!

It also applies to solids, liquids, vapors, smog, and partial vacuums.
If it's warm, it has molecules that vibrate. Now, how does mentioning
hot air prove the existence of electron waves?

Really? If transmitting RF radiates electrons, what does your
belching hot air produce? Pneumatic particles? Where' the analogy?

>>>Cathode rays were idenified in 1895.
>>
>> My antennas do not emit cathode rays. If they did, my neighborhood

>
>The cathode rays travel to the anode.

I have a cathode ray oscilloscope next to my radio. For some odd
reason, my radio fails to detect the cathode ray emissions. Perhaps
that's because an electron beam is not oscillatory and therefore does
not radiate in the RF regions?

>> Please produce a reproducible test, that will demonstrate that charged
>> electrons are being emitted by an antenna. Your Nobel prize awaits
>> you.
>
>It was done before the first Nobel prize.

Well, if the Nobel Prize is insufficient, permit me to offer a
different prize, for which you seem qualified:
<http://en.wikipedia.org/wiki/Pigasus_Award>
Should you actually write a paper or produce an electron belching
transmitter, methinks this award would be more appropriate:
<http://en.wikipedia.org/wiki/Ig_Nobel_Prize>
<http://www.improb.com/ig/ig-pastwinners.html>
You may need some help with the form and structure. I recommend the
Journal of Irreproducible Results as a suitable guideline.
<http://www.jir.com>
For example:
<http://www.jir.com/turboencabulator.html>
Be sure to include me in the credit for inspiring your research:

>They travel into the earth.

Somehow, I've failed to notice electrons piling up on the ground.
Presumably, you're suggesting that they are falling from the sky due
to the effects of gravity. Well, that might explain my inability to
work DX with my ungrounded antenna, but does not explain how radio
functions in outer space, where there is no earth ground.

>>>For this reason the all electronic equipment have the
>>>earth/chassis/counterpoise as e remedy.

>> operation.

>Totally wrong. The power lines and receiver antennas must have ground
>connection.

Simply stating your conjecture, and quoting outdate and erroneous
conjecture does not make it correct. As I previously asked, can you
produce an experiment that would conclusively demonstrate that
electrons are being produced by RF transmissions, and that RF
propagation ceases when the antenna ground is removed? Please keep it
simple, like explaining how an ungrounded balanced dipole functions.

>"The wire antennas used with crystal receivers are monopole antennas which
>develop their output voltage with respect to ground. They require a return
>circuit connected to ground (earth) so that the current from the antenna,
>after passing through the receiver, can flow into the ground. The ground
>wire is attached to a radiator, a water pipe, or a metal stake driven into
>the ground.[4"

Congratulations. You've discovered the counterpoise. That's a good
idea (but not necessary) for a monopole, where the grounded
counterpoise forms the missing element of the dipole. However, that
doesn't demonstrate or prove anything about other antennas, most of
which have little use for an earth ground.

>
>In EM is "electron fluid". In science "electron gas".

The only electron fluid that is currently valid is in plasma physics,
which has little to do with RF transmission. Could you kindly
enlighten me as to how one derives RF emissions and propagation from
plumbing? I couldn't find anything using Google.

>> I'm sure the teachers in this group will be thrilled to know that what
>> they're teaching is not science.
>
>Jimp is a teacher.

For a short time, I was a substitute teacher. I only taught one high
skool science class for 2 days. However, I taught science, not
technobabble.

Everyone lies, but that's ok, because nobody listens.

>Here no conflict. The hydraulic analogy is enough for kids.

It's not enough for me. Please explain how plumbing can be used to
demonstrate RF transmission and propagation.

I can see that I'm making no progress at showing you the error of your
ways. Methinks it's a hopeless task. I have a computah and a radio
to repair on a fairly hot mountain top and will be too busy to debunk
your rubbish. Please carry on without me.

I can address that but, alas, not with encouragement.

When I was working, my domain included Navy shipboard antennas, including broadbanded HF transmit antennas, fed by banks of four or eight couplers through 50-ohm Heliax. (Yes, I know your application is receive-only. Please stick around.)

When a ship had the usual three antennas, they covered the range of 2-6, 4-12 and 10-30. At each one's feed point, a fixed, passive matching network using two, three or four reactive components brought the antenna inside the 3:1 circle on a Smith chart. (We didn't adjust them, we just periodically inspected and tested them. Why, Ye-es-s-s, we usually found loose, missing or corroded hardware on the mast. Why do you think we climbed up there?)

I mention this because the Navy tried to get better by doing HF transmit using only two broadbanded antennas (2-9 and 8-30) but had to relax the spec to a 4:1 SWR. It worked on a few ships, but the radiomen often encountered freqs that were difficult or impossible to tune, so they'd revert to a whip antenna with a base coupler, like the Harris RF-601.

A good passive matching network for 2-30 seems unlikely. The Navy would have bought them by now if "surely such a thing exists."

Message-ID: <Hn1lr.16060$FQ1.9878@newsfe12.iad>
Source record: 2191

1. Is there wire with camoflage insulation? (just kidding!)
I plan on using wire with beige or tan colored insulation. I
think sky blue or grey would provide the wrong contract.
Any ideas on this?

2. The far end of the antenna will be hanging from and in
the branches of a tree. I will only be running 5W (if I'm lucky)
and wonder about the voltage at the end of the wire. Will some
heat shrink provide suitable insulation to prevent corona from
starting the bush on fire? Is there a better idea? I will be
using PTFE (Teflon) insulated wire.

3. I'll be running the wire from inside my suite through
a 1/4 inch hole in the aluminum window frame. I was going
to feed it through a plastic straw to prevent chafing and
possible short circuiting. Any suggestions on the best way
through the hole to prevent any problems?

4. Is there a way to tell if the glass in my windows
has some property that greatly attenuates signals?
I'd ask the management but I don't want to trigger them
into realization that future QRM will probably be
emanating from my 'shack'! I plan to work the world
while remaining invisible to those around me. If asked,
I'll just explain that the wire is an antenna for my short wave
receiver!!!!

This is the first time I've had to use a store bought rig!
Until now I've either had modified surplus or burned out
rigs which I rebuilt. I've always been an advocate of
low power, but real QRP is new to me too -- and I equate
it to the difference between dynamiting ponds and fly fishing!
Time will tell! :-) When I became ill I gave away all my
50+ years accumulation of valuable ham radio equipment,
tools, test equipment, and books -- collectively A.K.A.
"Junk". It's fun starting from scratch -- at least my shack
is not a terrible mess -- YET!

Do folks still mail QSL cards? Or can I settle for emailing
a graphic equivalent of my own design? I've been off the air
for a couple years now and think that things may have changed
while I was out of the picture. This is not a big problem as
printing and using the local buro shouldn't be too much of
a problem. The hundreds of rare QSL's coming into my
mailbox my invite unanticipated curiosity from the
management.

Thanks in advance for any ideas you may have. This
is the first time I've run through a metal window frame or
dropped the wire into and among the branches of a tree.

Dunno.. From what I notice, lighter colors may blend with the
sky at times, but they also reflect light more, which can cause
the wire to stand out more at certain times of the day.

>

No problem with that.. 5 watts is not enough power to start
anything on fire.. Even 100w will have trouble doing that in
most cases. Only when I was running high power have I noticed
arcing and burning of tree branches touching the ends of antennas.
You can use almost anything as an insulator and should have no
problems with QRP.

>

Low power can do fine if the antenna is decent.

>
> Do folks still mail QSL cards? Or can I settle for emailing

I don't do QSL cards myself.. In fact, I've never sent anyone a
QSL card ever.. And I don't need any to send me one, but of course
still many do.. The CW contacts are much more likely to generate
QSL cards than the typical phone jabber..
The way I look at it, is I know I worked the people.. I don't
need paper proof of it.. :/
Maybe you could get a PO box, and assign it as your new mail
address, and have someone check the mail every once in a while.

I've considered that. The stretch from my window to where the
wire will enter the tree is such that there will be no one below, and
anyone walking in the area and looking up will be looking mainly
toward the building which is various shades of brown. The chance
of anyone seeing the wire against the sky is very small if at all. I'll try
that
light brown or beige first but it will be easy to change. The only
real time involved has been in planning what to do.

Until something better comes along, reinforcing the wire with some
heat shrink tubing, and running it through a heavy soda straw should
do the trick -- in fact now that I think of it, you can buy heavy straws
for kids and I'll pick one up tomorrow.

I'm still not sure on that either -- I've heard that leaded glass
can be a problem, but I'm not even sure what kind of glass is
in these windows. As it is, I'm not pushing RF through the
windows, but have considered a small magnetic loop located
inside, in which case I'd like to know.

I have a chum who was running an FT-101 here in town
through a G5RV 3 feet or so above his roof. He was one of
the top DXers in town. One day he suggested that things weren't
quite right so I went over to have a look. I told him to tune up
whilie I watched. He went through the correct tuneup procedure
as per the book, but never readjusted the Carrier Level adjustment
when he began operating. I had him repeat the procedure and
the same thing again! It turned out that the Manual doesn't really
tell you what to do beyone the tuning point so he left things as
is, and worked mucho countries running only 15 watts! It

goes to show what lower power can do, and also that what you
don't know won't hurt you!!! Once, in my shack, I set my rig
on 20m with about 5 watts of output. I made a call, and got
an immediate answer from a fellow who I had elmered back
in the early 70's!!!! We'd lost touch for all those years and had
been looking for each other. I was here in Calgary, he was down
in Silicon Valley!!

I seldom QSL'ed unless requested, but I do a lot of CW work
(almost as much as phone) I'll play it by ear in the meantime.
One sad thing about QSLing -- when I got ill, my brother and
sister had a big sale and sold a lot of ham stuff (the rest I donated
to the local ham club). Some stuff that I would like to have kept
disappeared -- whether sold or not I don't know and never will,
but my collection of QSL cards going back to 1958 and over
four callsigns went somewhere -- my logbooks too! Such is
life, but I'm just lucky to be able to start life over again and have
the fun of doing it! This is really net -- back to basics and
climbing the ladder again! At least I never had DXCC to lose!

No, but you can easily dye vinyl or PVC insulation in whatever colors
you find useful. I once built a wire striping machine, that produced
a red and white "candy cane" pattern. Please don't ask why.

>I plan on using wire with beige or tan colored insulation. I
>think sky blue or grey would provide the wrong contract.

I think you mean contrast, not contract.

There are vendors that sell "stealth" antenna wire. It has a copper
plated steel core wire and clear insulation. Or, just the copperweld
wire, and no insulation.

>Any suggestions on the best way
>through the hole to prevent any problems?

If you drill through the wall, drill at a slight angle so that water
will drain out of the wall, rather than into the wall. Use PVC
electrical conduit parts for the feedthrough.

>4. Is there a way to tell if the glass in my windows
>has some property that greatly attenuates signals?

Yes. Read the label on the window. If it says Low-E glass, it's
probably coated with Titanium Nitride to reflect infrared. TiN is
about 40 ohms per square, which is highly lossy at RF. You can test
it with a cell phone. Compare the signal strength on both sides of
the window. If there's a drastic drop in level through the window,
you have Low-E glass. Note that all new construction and remodels in
California have required Low-E glass for the last 10 years or so.

Experience: I built a 10m sleeve dipole from copper pipe and I was justifiably concerned about voltage at the end where the feedline entered, so I encased the coaxial feedline in a length of PVC pipe. It acted as a separator.

This arrangement necessitated making one element larger than planned, so to accomodate the PVC, but it apparently worked. I never suffered an arc-through.

Today: If you were to secure the tree-end of your wire entirely within a length of PVC pipe, you would guarantee a separation of <enter PVC wall thickness here> millimeters from anything else. If you then glue some additional PVC fittings onto this "insulator," you can use them for mechanical attachment to <whatever> in the trees. Either that or hang the PVC from/within tree branches.

Good luck

"Sal"

I used to use a little FT-7 transceiver portable quite often,
and it was about a 20w input radio, and did about 10 watts out
on most bands.
Using any decent antenna, I never had any trouble working the
people I wanted to, and this was usually on 40 and 80 meters
using NVIS paths.
I remember one time I was camping out at Lake Amistad near Del Rio,TX.
I rigged up a dipole for 80m, and had it hanging between two short
trees. The antenna was only about 5 ft off the ground it's whole
length. Even with that low antenna, and the appx 10w output on SSB,
I was still in the S9+ range to most of the various people I was
talking to in say San Antonio, Dallas, etc..
For those type conditions, I would generally prefer 100w, but 10w
will usually get it done if need be. Only on the noisier nights
might it be a real issue where the extra power is needed.
These days my portable rig is the 100w Icom 706mk2g. And of course,
I can adjust the output power level to whatever I want.. I think the
minimum it will do is around 5 watts or so.. maybe slightly less..
But unless I'm worried about my battery, I let it rip at 100w..
The battery is rarely an issue as I usually can charge it off the
vehicle every once in a while.

Sal and Jeff, (and Mark)

Thanks for your thoughts and input on my intended
system.

Jeff -- I did mean contrast -- my darned keyboard is
getting old and confused, just like me!

I just want something quick and cheap so I've ruled out
anything like copper clad steel and such. In my years of
antenna experimentation, I would set up the system, test
it, and even though it worked well, could not resist the
temptation to 'fix' it by tearing it down and setting up a
new and supposedly improved MKII version. I never
got much more gain or efficiency, but still had fun.

Just to clear things up on the geometry, the wire will run
out the window horizontally to the tree (about 25 ft) and
then drop vertically (another 25 ft approx) through the
tree to just above the
ground. Sort of an inverted letter "L". It is just a
random wire, and the best I can do at the moment
given my current situation.

The hole through the window frame is too small (1/4 in.)
for conduit but I plan to use a heavy plastic kids drinking
straw, tilted down on the outside, and plugged with some
silicon seal at each end where the wire enters and exits.

That reminds me of a friend who drilled horizontally through
his foundation and drove an 8 foot ground rod through it.
The first rainfall seemed to find it an ideal means of
draining the back yard into his basement and he ended
up with about 4 inches of water in his basement!

Jeff -- thanks for the tip on testing the glass. I can't see
any markings on it, but the test is quick and simple and
will soon let me know if I want to follow up with antennas
inside the window. I may even try loading the window
frame (aluminum, 5 ft x 5 ft (approx)) using a handy
sheet metal screw for the connection.

Sal -- I've built a number of monoband sleeve dipoles by
simply sliding back the braid on the coax. They were always
great performers, but in this case I think they might be
too obvious -- stealth is the primary concern here.

A reminder -- the ground system will be tuned counterpoise wires running along the wall inside my apartment. I have an MFJ-1623 tuner which will handle tuning the antenna and the counterpoise in a very nice compact arrangement with only one meter to watch!

Mark, NM5K has already calmed my concerns re corona and a reenactment of the burning bush bit, however I will cover the last few inches of the dangling portion with some heat shrink tubing, A small loop in the end will allow me to fasten the end with a plastic cable tie.

I'm really having fun with the planning stage -- with all this taken care of beforehand I will hopefully be up and on the air tomorrow. Only one factor can hold me back, and that is that the sale of my condo concludes tomorrow, and at the same time we have a very much contested Provincial election -- the equivalent of your state elections. In between I hope to gather the necessary materials and get operational.

Thanks again guys for your trouble and assistance. It's all food for thought and I appreciate it. I'm really having fun and don't even have any wire out the window yet!

Will your 25ft span of copper wire support a few birds? If not,
please reconsider copperweld.

Do you have an antenna tuner? The FT-817ND does not have a built in
antenna tuner. You're going to need one with your random wire and
random configuration.

>The hole through the window frame is too small (1/4 in.)
>for conduit but I plan to use a heavy plastic kids drinking
>straw, tilted down on the outside, and plugged with some

Ummm... is this an existing hole are you going to drill a new hole?
The modern windows that I've seen have the glass extend almost to the
edge of the frame with only a sheet rubber spacer in between. You're
highly likely to drill through the glass if you decide to drill the
frame.

>I may even try loading the window
>frame (aluminum, 5 ft x 5 ft (approx)) using a handy
>sheet metal screw for the connection.

With 5 watts, that might work. Forget about building a magnetically
coupled loop. You would need to split the frame at some point, and
install a variable capacitor. That's probably not going to happen.

If your window proves to be uncoated glass (unlikely), you might
consider two squares of aluminum foil on both sides of the window to
couple through the RF via a ladder line. You won't get much
capacitance so it won't work on the lower frequencies, but should be
tolerable for the higher bands.

>A reminder -- the ground system will be tuned counterpoise
>wires running along the wall inside my apartment. I have an
>MFJ-1623 tuner which will handle tuning the antenna and
>the counterpoise in a very nice compact arrangement with
>only one meter to watch!

Good, you have a tuner. However, that's designed specifically to handle a 12ft balcony mount HF antenna. I don't know what it will do with a longer antenna. Looking at the schematic:
<http://www.mfjenterprises.com/pdffiles/MFJ-1623.pdf>
it seems to be a crude L match, which isn't going to match every combination of reactance and frequency. The meter does NOT indicate VSWR, so you really won't know if the tuner is effective. My guess(tm) is you're going to purchasing a more elaborate antenna tuner, a VSWR meter, or using a 12ft piece of wire.

I once used a large sheet of WELDED chicken wire under the carpet for a "ground". It has to be welded to prevent the galvanizing from forming diodes. It sorta worked but nobody wanted the lumpy carpet.

"The photoelectric effect will cause spacecraft exposed to sunlight to
develop a positive charge. This can be a major problem, as other parts of
the spacecraft in shadow develop a negative charge from nearby plasma, and
the imbalance can discharge through delicate electrical components. The
static charge created by the photoelectric effect is self-limiting, though,
because a more highly charged object gives up its electrons less
easily.[53]"

Heaviside derived RF emissions and propagation from the plumbing. RF are the
rotary oscillation.

How can a counterpoise or chassis serve as an infinite source of
electrons? When your theory would be right, the counterpoise would
get charged just like the antenna. In reality this does not happen.

The counterpoise only serves as a place to dump AC current (the output
of the transmitter) during the cycle of radio frequency output. It is
not (and does not need to be) an infinite source of electrons because
elecrtrons are not emitted by the antenna.

You see that you can make spelling errors yourself.
Maybe you should consider that when making fun of other people's
spelling errors.

I do a fair amount of camping with portable operations and have an 80m loop and end-fed zepp at the house in a residential area with no restrictions. Actually, the black or copper wire (when it starts turning from shiny) is the less visible of all, either against sky or trees. My ef zepp is white with blue stripes and it actually glistens at certain light angles. You actually have to look to find the loop in the yard and it is 294 ft long, made of #16 gauge copper clad.

> a 1/4 inch hole in the aluminum window frame. I was going
> to feed it through a plastic straw to prevent chafing and
> possible short circuiting. Any suggestions on the best way
> through the hole to prevent any problems?

With a 1/4 inch hole, actually might be less, you could run a very short piece (a few inches/cm) of r8x, r59, r58, or any of the smaller coax and simply trim off the shield at the end and use the middle conductor for the wire. Also, small rubber, teflon, or plastic tubing such as used in model airplanes might work.

I use parallel pieces of coax with shields soldered together and connect my open wire feed to the center conductors to get under my metal framed window. Actually have a strip of wood with holes for this and close the window down on that strip of wood. Of course in the winter up in AB you have to be more careful with cold air than we do in Louisiana. hi

Will listen for you on the air. Good luck.

It's a new hole -- two days old now though. I am using an MFJ-1623
tuner which also includes tuning for the counterpoise ground which I'll be
using.

The wire will be enough to hold one small bird -- if necessary
I can always rebuild with heavier wire (the MKII version
I mentioned before)!

I checked carefully before I drilled and missed the glass
entirely which is unusual because Murphy lives with me! I've
never seen him, but his influence is always around!

The magnetic loop would not be using the
window frame -- I have some 1/2 inch flexible
copper tubing which I brought from my condo
(which will officially be off my books at noon today!)

Last week we had a flea market in Calgary. Having given
away all my precious ham radio parts (aka junk) I was in dire
need of a roller inductor and a variable capacitor or two
to build (if necessary) an artificial ground, or a matching
device of some sort for whatever purpose I might dream up.

I walked into the market, paid my admission, and the first
thing I saw was a box (about 4 cu ft) of variable caps of
assorted shapes and sizes. I bent down to have a closer
look since I could hardly believe my eyes, and asked the
seller 'How Much?' At the same time, I noticed another
box of the same size full of assorted inductors, some
roller inductors, some coil forms, some coil stock and
such. It was like a dream come true. The seller
responded '20 bucks for the whole box' and I asked
'How about 20 bucks for both boxes' and he
accepted! Talk about a lucky find -- some of that
stuff is hard to find nowadays, and to purchase would
cost a fortune. I have both boxes in the trunk of my
car as there is little room in my suite to allow me to
start collecting parts aka junk! I've brought the cream
of the crop up to my suite and have cleaned them off
using an electric toothbrush and a mildly abrasive
cleaner -- they look like new. I now have sufficient
L and C, both fixed and variable, or every sort and
description to keep me happy for a long while. The
rest I will store in my brother's garage until the next
flea market where I intend to recoup my $20 bucks
plus the admission price!

I've tested the MFJ-1623 and it will work 80 thru
10M with the wire -- the wire is basically the same as
the 12 foot whip only longer but thinner. If it doesn't,
I have another MFJ-949E which I got as junk because
the coil switch was burned (I replaced it in an hour
with a new single pole 12 position) and it's been
tested and used by a friend of mine for the last
couple years. If one or the other works or doesn't,
I've got all that LC stuff from the flea market so
if necessary I can put together enough to load a
wet noodle.

I did load a wet noodle once, and worked from
Penhold AB to Red Deer AB (about 10 miles)
just to show it could be done! I love antennas.

Does anyone recall reading a book on antennas
that had a Chapter subtitle saying 'Antennas are
Funny People!'? I'd love to find the book again.

My carpeting is wall to wall, so the chicken wire
ground would have to be on top of the carpet. I'm
sure though, that if anyone asked, I would simply
explain 'I'm a Ham' and they would shake their
heads understandingly and not ask any more
foolish questions!

One way or the other, with the planned
setup, I intend to get some signals out -- come
hell or high water. I don't give up on my hobby
after all these years, and I've helped many a ham
get on the air under worse (but not much worse)
circumstances.

Gotta get downstairs and vote -- we are having
our provincial election today!

This first antenna here is going to be quick and simple with Tan
colored wire. If that doesn't work, the MKII may incorporate
your suggestion!

I considered the coax feed through but would prefer it all be one piece of
wire from the tuner to the end. Thanks for the suggestion though.

When I had my house, I had so many holes drilled in my basement window that the frame looked like a strainer. I ran open wire and used the same arrangement for my open wire feeder -- I've always liked open wire -- it permitted so much more than a coax fed antenna system.

Thanks again for your assistance!

Attach a spring to the end of the wire. That will take up the slack
and help absorb the impact of the bird when landing on the wire. If
you don't mind reinstalling the wire occasionally, attach a thin
sewing thread on the end of the wire. When the bird lands, the thread
will break, not the wire.

>I checked carefully before I drilled and missed the glass

You were lucky. Try not to rely on luck.

>10M with the wire -- the wire is basically the same as
>the 12 foot whip only longer but thinner.

Yep. I would expect it to work with the 12ft antenna it was designed
for. However, you were suggesting a 50ft long antenna (with a tree in
the middle), which might not work.

>If it doesn't,
>I have another MFJ-949E

<http://www.mfjenterprises.com/Product.php?productid=MFJ-949E>
That's much better.

>My carpeting is wall to wall, so the chicken wire
>ground would have to be on top of the carpet.

I've snuck flat CAT5 cable under wall to wall carpet for wiring a LAN
(for internet connectivity). A steel wire snake, a carpet kicker, and
an assistant, was all that was needed. Could could do the same with
thin copper wire and never see a lump.

>I'm
>sure though, that if anyone asked, I would simply

Hint: It's much easier to ruin your reputation than it is to improve
it. Methinks it best to look and act normal for a few weeks, and then
surprise the neighbors, than to do the reverse.

They work like the receiving antenna of the cristal radio. Electrons from
the air go into metal.

Counterpoise is exactly like underground "ground". But if the soil is dry
sand or the rock there no free electrons. It is better to place the
conductors in the air.

> When your theory would be right, the counterpoise would

It is not my theory. It is Marconi antenna and his theory.

Where the voltage is there must be the electron emission.

Experiments with the photoelectric effect shown that no current below 10V.
But it apply to the flat cathode.
If the cathode is a wire the voltage is lower.

And what is with your antenna in sunny day?

That is not what an antenne does.

But they are not connected to a source of free electrons, so if those
would be required they would be depleted pretty quickly.

Even if there are a couple of electrons that jump off the antenna, it is not going to cause a measurable effect. You need more than a couple of electrons to have a measurable current, and it is not going to happen at those voltages and daylight conditions.

Calgary, is that right? Do you need to allow for snow, ice and wind in designing your antenna?

I have had good luck while camping, with transparent fishing line at the end of antenna wire. It has some stretch, is easy to tie to tree limbs, etc. And a spool will last forever.

Unless you have other ideas for the window hole, put the wire through and use a hot glue gun to seal the hole. If you can reach both sides of the hole, do the same on the outside. RTV also works.

Good luck. Paul, KD7HB

Thanks Paul,
I never thought of it, but some monofilament (I'm a sport fisherman) will
fill the bill. Until now
I've always used parachute cord but don't have any anymore. I plan on
sealing the hole at
both ends with RTV. Hopefully the wire I use will stand up to the harsh
Alberta winters,
all my antennas have so far, but if need be I can readily replace the wire
with very
little effort. According to my calculations, which include Murphy's Laws,
the
antenna should stay up until minus 40 degrees, a windstorm, and blowing
snow occurs -- and according to Murphy it will all happen in the middle
of a QSO with some extremely rare DX!

Personally, I have always found Murphy to have been somewhat of
an optimist!

Thanks again for the suggestion,

Irv VE6BP

The selfcapacitance of an antenna is very small. You need a couple of
electrons to have a measurable static voltage.
For this reason the earth/chassis/counterpoise is necessary.

Hello Szczepan.
A dipole aerial doesn't need a counterpoise nor does it need any connection to earth/ground/counterpoise.

I've kept quiet during the discussion because I don't think of my radio and aerial in terms of sub-atomic particles. For me, resonance, impendance and SWR are more significant.

Have you considered taking your theories / discussions / cutting-and-pastings about sub-atomic particles and other kindred items to one of the physics newsgroups such as:
alt.sci.amateur
alt.sci.physics
sci.physics
I'd expect that you will find lots of people with whom you can discuss the behaviour of sub-atomic particles.

Kindest regards, Ian.

Your dipole are exactly like the two Kundt's tube. There are "resonance,
impendance and SWR". To demonstrate of the SWR the tube end must be porous.
Air molecules work like the electrons.

Electrons are the subatomic particles.
Radio is the only field where "plumber analogy" is totaly inadequate.

Kindest regards,

Definitely not. That's a full wave aerial. It's an FM transmitter. I use SSB
and CW.

The ends of my aerials are not porous.
According to Wikipedia, Kundt's tubes are used to measure the speed of sound
in a gas or solid rod.

Have you considered taking your theories / discussions /

1106. Indoor Counterpoise For Random Wire Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2012-04-24 22:08:10 UTC
From: Irv Finkleman <finkirv@shaw.ca>
Message-ID: <avFlr.12829$M37.3779@newsfe01.iad>
Source record: 2073

I am using a random wire antenna which runs outdoors through a hole in a window frame.

I do not have access to any good RF grounding system and plan to use an indoor counterpoise wire from the ground connection on the tuner (MFJ-949E). I have a nice role of #18 wire, the end is connected to the tuner, and it is my intention to unroll it along the floor through my suite until such time as it is properly tuned.

MY QUESTION IS - How can I tell when I have unrolled the right amount of wire for the frequency in use. I know it will not be 1/4 wave, and that it should be less.
From what I understand, when it is adjusted properly I should not have any hot RF burning my lips from the mike. Checking it with my lips is not what I call a desireable means of testing, and being single I cannot call my wife to test it for me. I'd like to find a better way and hence my questions.

I believe (according to what theory I have learned) that the tuner chassis would be hot with RF, with the amount of RF becoming less and less as the counterpoise wire approaches the proper length. If this is true would a simple RF sniffer tell me?
I can rig one up fairly easily.

OR - What would I be looking for using my MFJ-259B SWR Analyzer? I expect what it would show readings similar to a dipole with resonance at the operating frequency and an impedance (resistive) of somewhere in the order of 60 ohms. plus or minus -- is this a correct assumption?

OR -- does anyone on the group have any suggestions that will tell me when the system is properly adjusted -- the simpler the better!

Once I have found how to do this, I can put tape markings on the roll of counterpoise wire to show the appropriate length for each band or narrow band of frequencies in which I will be operating.

I have already tested the hole -- it is just a little less than 1/4 inch diamater,
but that seems to be enough to let both sidebands through -- I carefully tested
that using AM which proves that two sidebands can fit through the hole at the
same time, which allows me to further assume that either the upper or lower sidebands should squeeze through easily! :-)

Thanks in advance for any assistance you can provide in this matter.

Irv VE6BP

On the air finally but afraid to get to close to the mike! I may have
to use rubber gloves and teflon lip gloss!

Since you started this whimsical line of reasoning, you dare not object:
Buy a plastic microphone. Har-har-HAR-dee-har-har! [Thanks to Ralph
Kramden]

But seriously folks ...

You do have a coaxial cable from the radio to the tuner. Choke the
bejabbers out of it. Either wind the coax itself into one or more physical
coil(s) of the right proportions or use the W2DU method.

This will be useful for the former approach:
http://www.karinya.net/g3txq/temp/choke_impedances.png
It illustrates that no single coil really does it.

... and this for the latter:
http://www.qsl.net/ta1dx/amator/W2du.jpg
Although your application doesn't involve using beads as a balun, per the
illustration, the broad approach is the same: blocking common mode currents.

"Sal"
who chokes his cables and gets no shocks

You shouldn't need to unroll the wire at all since you're using a tuner.
Just hook it up and tune away.

Irv,

I think you will find it difficult to tune up using a MFJ-949E, random wire antenna and a roll of wire run around your apartment. You will probably end up with a "hot mike" most of the time. Even if you get it all tuned up on one frequency as soon as you QSY to a different frequency you will have to change the counterpoise wire length. Finding the right lengths for different frequencies and coiling/uncoiling the wire each time you QSY will get old fast.

I have a better solution for you. Buy an MFJ artificial ground so that you can use a fixed length of wire under the carpet and tune the counterpoise from the operating position. MFJ makes a standalone product called the MFJ-931 or a tuner that includes the artificial ground - MFJ-934. Here are some links to these products:

http://www.mfjenterprises.com/Product.php?productid=MFJ-931
http://www.mfjenterprises.com/Product.php?productid=MFJ-934

Hope things work out for you and that you get back on the air in the near future. Let us know how things work out for you.

Roger

I once had the little B&W vertical in a 3rd story apartment window. To
tune it, I used an SWR meter and simply unrolled my single
counterpoise wire across the rug until the swr was 1:1 for the band in
use. The counterpoise was on a wire spool. I never actually measured
the counterpoise length -- I simply found 40 meters meant the wire
went from the bedroom window to the kitchen.

Source record: 2077

Thanks Sal, Roger, and Bob as well as
the many others who have not yet replied
-- actually my mic is plastic.

I truly appreciate your assistance, but I think
I really need to explain my rationale somewhat.

The real intent of my questioning is to provide
a counterpoise system whereas the tuner does
not just have an unbalance by simply feeding
the random wire, but a balance achieved
whereby the counterpoise connected to the
tuner acts as the other (missing) half of the
unbalanced system, thereby balancing it just
as the ground image does with a quarter wave
antenna. Does this make sense? If not, wait till
you read further about MFJ and the push and
pull explanation.

I have two tuners at my disposal -- one is an
MFJ-949E Deluxe Versa Tuner II -- a common T
match configuration. The other is an MFJ-1625
Window/Balcony Mount Antenna which contains
matching circuitry and also a loading coil
for tuning the counterpoise wire or wires.
I hope to use the 949E, if I can resolve the
matter of knowing when the counterpoise
is properly adjusted. It is this matter that
I am trying to resolve to my satisfaction. I
could equally use the MFJ-1625 which is
just an MFJ-1623 with a 12 ft whip and
an 80m loading coil.

I'm fairly well read on antennas, but still my
knowledge of this monumental subject is very
limited i.e. to me a Smith Chart is something
belonging to a hospital patient named Smith.
I sort of understand the concept of the
counterpoise acting as the missing half of the
system, but have difficulty putting it into words.

MFJ, in the MFJ-1625 Manual say....

QUOTE
It is always important to have a good RF ground,
provided by the counterpoise, when using any

whip or long-wire antenna. This is because the
MFJ-1623 tuner needs something to "push"
against in order to force current into the antenna.
If a good RF ground is not available, RF will usually
find its way back into the power line (RFI),
transmitter audio circuits (RF feedback),
or the operator (RF burns). Water pipes provide
good dc and ac safety grounds, but they are
often inadequate for RF grounding because they
are long single conductors. RF grounds
require large "spread out" surfaces with direct
multiple connections to the equipment ground
point. Water pipes, heating ducts, or multiple
ground rods may work (especially if they are all
connected together with jumper wires), but the
best RF grounds are radial systems or
multi-wire counterpoises.
UNQUOTE

I have to admit that this explanation contains
terms like long-wire antenna used in what I think
might be confusing or ill-defined ways, but the
idea of push and pull of antenna current feels
right. If this is not already confusing, it is the
MFJ-1625 Manual, but the tuner is an MFJ-1623.
Many hams use the term MFJ as standing
for 'Mighty Fine Junk', and at times I agree, but
I do have good skills as a technicial and find that
a little resoldering and tightening of ground nuts
turns it into somewhat better than any of the
homebrew or modifications I have ever put on
the air. I no longer have a house, shack, workshop,
and tower, etc,etc,etc and am now working with
largely storebought items and limited space.

I have considered a cabin in the mountains where
I would not interfere with anyone around, but where
would I find one with built in housekeeping and
meals? Just the expense of the extension cord alone
makes me shudder.

I am not as concerned about a case of 'rf lip' as I am
about stray RF causing possible problems with the
neighbours on all sides of me, with all my electronic
toys such as computers, DVD players, the local
fire-alarm system and other such things. The last
thing I want to do is draw attention to the fact that I
am running a ham radio station from my suite until
I know I am not causing any problems.

Thusly, my goal is to provide myself with a first rate
RF ground system, entirely contained within my suite,
in order that I do not wake up at night with the fire
alarms set off and great numbers of disturbed
residents gathered around pointing at me and saying
'Ham! Ham! For Shame! For Shame!' and the Residents
Council having special meetings to decide how to deal
with me. They already think I'm crazy -- and I may be
somewhat, but I don't want to make matters worse!

So, having herein explained my rational, lets see what
help I can get in the way of producing the ideal indoor
low-cost non-radiating counterpoise radial system.

Actually, I have lots of wire for the radials, the
tuner contains a loading coil to assist in tuning
the counterpoise, and my big concern is how do
I determine when the counterpoise is operating
effectively. The metering system in the tuner should
reach a peak and subside on either side of the
correct counterpoise tuning point, and what I
really need to know is how to determine when the
stray RF is minimized if not eliminated.

I have to explain that I do all this in a somewhat
humorous manner, I find all my predicaments funny,
but then I brought myself into them and this is the
only way, short of outright denial, of dealing with them.

You have probably already noticed that I am a
man of few words!

Irv VE6BP

P.S. In a previous topic where the matter of electrons
escaping from the end of the antenna was hotly
debated, I have solved that problem by forming a
wee loop at the end of the antenna, thereby taking
any of those loose electrons and feeding them back
into the wire! I used the loop and a nylon cable tie
to fasten the end of theantenna into the tree which
supports most of it, thereby eliminating the cost of
a ceramic insulator and it's accompanying end effect.
I'm sure Tesla and Marconi could have used some of
my simple practical solutions like this one, and perhaps
negated the necessity of long discussions re electrons
escaping from antennas.

Yes and perhaps I have a workable idea to get there.

First, an assumption: Your long wire out the window frame has only a short run to the tuner. That is, the tuner is on the same wall as the window frame and is near the window. How'm I doing so far?

Along that same wall, stretch out a heavy piece of straight wire -- can be insulated but you'll cut through the insulation as needed -- from corner to corner. It's like a workbench ground bus but it's not grounded, per se.

Attach the tuner ground to it.

Buy two (maybe more) locking metal tape rules. Craftsman, Lever-lock. At the zero ends, securely bolt or clamp the metal tape rules to the ends of the heavy wire in each corner. Yes, you're ruining the tape rules by mutilating the ends but we know you're desperate. Courage, man!

Stretch out the tape rules until their lengths become whatever you need for a workable counterpoise, recalling that HF antenna elements (and counterpoises) do not need to run in perfect straight lines. Zig-zagging is your friend in a confined space. Even go up the wall(s) in the far corners.

This method, if it works, has a bonus. Once the lengths are established for each band, the exact lengths can be eyeballed directly off the tape rules and noted. Alternatively, just scrawl band numbers on the walls. (Hi-hi)

So you should not unroll it but have "all connected together with jumper
wires".

Jta is the same opinion: "You shouldn't need to unroll the wire at all since
you're using a tuner.
Just hook it up and tune away."
The hook = jumped wire.

There was also Sir Oliver Lodge. He demonstrated the escaping of electrons from the antinodes (see Fig. 2):

He also discovered that HF do not like the long conductors;
"The electrical charge stored in the Leyden jars could flow either through the very low dc resistance path provided by the loop of wire or it could flow across the very high resistance path through the air between the spark-gap terminals at B. It would seem that the obvious path for the charge to follow would be through the low resistance wire loop. Surprisingly, Lodge was able to produce very large sparks across the spark-gap, B, even though the dc resistance of the wire across the gap was only a fraction of an ohm.[4]"

I am trying to "descend you into the same bottomless pit"

Bang on Sal -- the tuner is located about 18 inches from where the
wire comes through the window, but on the floor along the wall
with the window is the baseboard hot water heating unit so I can't
really run anything on the floor along that wall. Similarly, although I
understand your tape measure idea, there is a simpler solution
which I tested last night and worked perfectly.

I arrived at a solution through the following note from Bob, K5QWG
who wrote:

"I once had the little B&W vertical in a 3rd story apartment window. To
tune it, I used an SWR meter and simply unrolled my single
counterpoise wire across the rug until the swr was 1:1 for the band in
use. The counterpoise was on a wire spool. I never actually measured
the counterpoise length -- I simply found 40 meters meant the wire
went from the bedroom window to the kitchen."

I thought it made perfect sense and even downloaded the instruction
manual for the B&W AP-10 Windowsill Antenna which told me the
same thing as Bob wrote -- and it worked perfectly.

I too used a spool of wire connected to the ground post on the
MFJ-949E tuner, and unrolled it away from the tuner and antenna,
across the floor and through the room. At that point I tuned up on
frequency, adjusted the tuner for minimum SWR (nearly 1 to 1)

and that was that! It worked beautifully.

Your idea with the tape measures would have worked as well, but would have been a little more expensive and possibly unworkable due to the heater. Instead, I simply put a tape marker on the counterpoise wire at the length where it worked well on the band tested (80M). Now, when I want to operate all I have to do is unroll the spool to the tape marker and Presto! I can go on the air! Of course I have noted the tuner settings, and will also add further tape markers on the counterpoise wire for the different bands, and note the tuner settings as well.

My next step may be to cut counterpoise wires for each band of operation and permanently lay them along the wall this negating the need to roll and unroll the spool of wire each time.

With time there may be some minor changes. For instance how far across the bands can I tune without any significant change in SWR. I might also try putting a loading coil in the counterpoise line at the tuner end so that I can fine tune the counterpoise length electrically. I will build up a little RF sniffer just to check for local stray rf but that should no longer be a problem.

I could use the MFJ-1625 tuner which has a built in switched coil to adjust the counterpoise, but it only has a current meter, not an swr bridge. The MFJ-949E tuner has swr metering. Therefore if the loading coil for the counterpoise works, I can use the 949E and sell (albeit at a small loss hopefully) the MFJ-1625 set complete to some ham who is able to operate using the intended setup for the 1625. It is an excellent system, but because of all the metal in my building which negates indoor operation, and the inability to put the whip out of the window due to physical limitations existing in my suite, I cannot use it. I had not considered the limittions in my situation prior to buying the 1625 but it was worth the try. I might even keep it (I may have to if I can't sell it) for portable use when I go fishing. It would be an excellent setup on a picnic table or from a tent. Again, time will tell,

In any event, A BIG THANK You to all who helped in this discussion -- I can now get on the air and as soon as I have things tested and tidied up I hope to meet you there.

Irv,

Nice to hear that you got something working and are back on the air. However I want to point out some incorrect assumptions you made earlier about RFI and stray RF from counterpoises.

The subject of radiating counterpoises in an apartment was discussed in this Usenet group a few years ago. Here is a link that provides some more info for you.

How much does a counterpoise radiate? - http://www.radiobanter.com/showthread.php?t=117807

The counterpoise you have inside your apartment will definitely radiate into the building as will the length of antenna running from the tuner to the hole in the window. In another post you said you were running QRP at 5 watts. You may not have any RFI problems with other electronics in your building at these low levels. If you crank up the power to 100 watts I don't think you will be so lucky...

Irv,

Your goals are certainly valid.

As far as preventing RF from going where you don't want it to... the main issue MJF is talking about here is "conducted" RF. The RF energy on the "ground" side of your antenna connector is going to flow outwards through every conductive path available to it, including the "counterpoise" side of your antenna arrangement, and anything connected directly or indirectly to your rig's chassis (e.g. to the power supply and then onto the third "ground" wire in the household mains). The amount of current flowing through each of these paths will depend on the RF impedance of the path, with more current flowing through paths of lower impedance.

So, what you want is (probably) to have one or more counterpoise wires whose RF impedance is as low as practical, at the frequency in question. These could be quarter-wave wires, or they could be shorter or longer wires with an "active ground" (which is essentially a simple "antenna tuner" on the ground side, with an adjustable reactance to

cancel out some of the reactance of a non-quarterwave wire).

You can also help keep RF "where it belongs" by adding common-mode chokes to your rig power cables, thus increasing the RF impedance of this path and helping reduce the amount of current which is conducted back into the building ground.

Another approach which may help, is to consider using an end-fed half-wave antenna, with a specifically-wound matching coil system. These are (in principle at least) largely ground-independent... the low-impedance side of the matching coil provides good RF paths for both the "hot" and "ground" sides of the antenna connection, and when properly adjusted they don't dump much RF into the rig ground or counterpoise.

These techniques may not help much, if at all, with *radiated* RF getting into places you don't want it. Even if you have an antenna which is fully balanced, and completely isolated from the building ground (e.g. battery powered), the "near field" RF from the antenna can be coupled into the building wiring, and start causing interference and "undesired operation". Unfortunately, a lot of consumer and industrial electronic equipment these days is very vulnerable to this... poor shielding/filtering. Speaker cables, telephone and alarm wiring, etc. can all act as antennas.

Not much you can do about this except try to route your antenna and counterpoise wires as far away from other wiring as possible, keep your transmission power down, and try to transmit during times when people are asleep.

However I want to point out some incorrect assumptions you made earlier
about RFI and stray RF from counterpoises.

The subject of radiating counterpoises in an apartment was discussed in
this Usenet group a few years ago. Here is a link that provides some more
info for you.

How much does a counterpoise radiate? -
http://www.radiobanter.com/showthread.php?t=117807

The counterpoise you have inside your apartment will definitely radiate
into the building as will the length of antenna running from the tuner to
the hole in the window. In another post you said you were running QRP at 5

watts. You may not have any # RFI problems with other electronics in your building at these low levels. If you crank up the power to 100 watts I don't think you will be so lucky...

-
True. A few years back with 100 watts and an attic loop, I fried the solid state heat/AC thermostat. I put a ferrite choke on the leads of the new one.

Source record: 2084

Thanks Roger -- I already knew that but didn't at all consider it during my recent explorations into the counterpoise system. How I managed to ignore it defys explanation -- I keep asking myself how that occurred. I think it may have been a cross between psychological suggestion and some form of denial in wanting a good and clean signal.

In particular I really enjoyed the tipoff to RadioBanter.com which I intend to explore more, and the discussions were informative. In particular, where there are links to other threads I found some of Reg Edwards material which has always been worthy of reading.

I went to bed satisfied that I could now get on the air and not set off any alarms etc, and although I don't recall them when I woke up, I'm sure I must have dreamed about good times on the air again! I've been in and out of the hospital for a couple years and have not been on the air since about mid 2009. I'm better now and looking forward to lots of radio activity!

As I mentioned in earlier posts, I have never been power hungry and have generally operated in the under 25 watt range -- now I'm going to be what I call 'ham flyfishing' i.e. QRP.

Now I can do some further experimentation such as using individual counterpoise wires for each band, and possibly even a variable inductor to fine tune the counterpoise, and assorted things like that. I have never been as interested in operating as in the technical aspects -- especially the eternal search for the utopian small antenna/DX magnet. My DX interest extends only in so far as it is the on the air tests that tell you how well your antenna system is functioning given a non-adjustable set of propagation conditions.

Now I have only to look forward to a good sunspot cycle and perhaps just a little more global warming to help me through those cold Alberta winters!

What's your call? Where are you located?
I saw a .ca somewhere but that doesn't tell me

much.

Thanks again,

Irv VE6BP

Gonna ham away my 'golden years'!

Irv,

If you found the radio banter discussion interesting you will really enjoy the forum on restrictive antennas at eham. Pages and pages of stuff written by hams living in condos, HOA and apartments. Here is the link....

http://www.eham.net/ehamforum/smf/index.php/board,2.0.html

Now that you are feeling better you can start having some fun back on the bands. You might find some of the digital modes like PSK31, WSPR etc. fun and they don't generate "recognizable RFI" like CW and SSB.

Leyden jars? You're back that far? That's over 250 years ago! They
had no idea of RF then!

You really need to look at things that aren't so old. The authors you
are reading have been proven WRONG when it comes to antennas and a good
bit of everything else related to electricity.

Thanks for your reply Dave,

I'm learning a lot in a hurry, finding out that grounds can be just
as complex as antennas, and all about the interelationship between
the two.

I do have chokes on the power cord of my 12v supply and
also on the supply cord between the PS and the rig.

Your half wave suggestion is not immediately forthcoming
due to the physical limitations I face here however it is
on my list of possible future condierations.

As per a previous post I have recently come into a
treasure trove of inductors and capacitors -- variables
of every type and sixe. With all this at my disposalI
plan to fiddle about with tunable counterpoises,
artificial grounds, and combinations thereof.

At least I'm on the air again, but because I gave
all my gear away I've had to jump from old tube rigs
into a QRP world with a teensy Yaesu Ft-817 that it
appears will take some time to learn to operate with
all its menus, settings, and such. I have to get new
glasses and perhaps a magnifier too.

The saving grace here is QRP with which I hope
to get into as little trouble as possible.

I'm a pretty good tech, and have fixed up and modified
lots of stuff but now I'm going to have to do a lot of
learning in the wild world of wire antennas and grounds.

Thanks for your good suggestions, and for taking the
time to reply.

Thanks Sal -- I don't know what was happening -- it had
me wondering. Darned newfangled computers! :-)

I'm spending the morning learning how to operate this little
Yaesu FT-817ND -- it's going to take a bit of patience with
all the menus and settings. I have a TS-820 I fixed up and gave
to a chum who upgraded to a top of the linke TS-1Million or
something and he offered it back to me. It would be a lot
simpler, but one slip of the carrier or mic gain and I'm sure
I'd totally reveal my thus far cleverly concealed ham radio
operation!

Thanks again for getting back to Tom on the Leyden jar matter!
It really had me confused.

No parts were missing any time the antenna was in use. I was able to
fix the storm damage myself. The parts were lost during subsequent
storage while I was overseas. Anyhow, all's well that ends well.

Yes, I'm sure. Neither of your links even mention electrons. You may
want to elaborate a little on why those two link are relevant.

As I previously mentioned, there are many ways to detect electrons,
such as a phosphor screen (CRT), electrometer, or a Wilson cloud
chamber:
<http://kennethfinnegan.blogspot.com/2010/12/build-your-own-cloud-chamber.html>
(Hint: Don't drink the alcohol). None of these tests will respond to
RF from an antenna.

Thanks. I turn on my ancient Icom IC-735, tune around 20 meters and
hear nothing. Transmit and I get infinite VSWR. Ok, something is
wrong. After 15 minutes of juggling coax cables, spinning knobs,
pushing buttons, and head banging, the light comes on in my head.
After a nasty wind storm in January, I a tree had destroyed most of my
antenna farm, which I haven't repaired. Rebuild antennas now added to
the things to do list.

Light reading on the FT-817:
<http://www.ka7oei.com/ft817pg.shtml>

>The saving grace here is QRP with which I hope
>to get into as little trouble as possible.

As soon as the neighbors find out that you're a ham radio operator,
several things will happen.
1. You will immediatly be blamed for all manner of electronic
failures. Kitchen appliances, computer crashes, and prematurely dead
batteries will all become your fault.
2. Neighbors will assume that you fix things for free. Training the
neighbors to pay for your time will be a challenge.
3. The phone will ring at 2AM asking if you're on the air and causing
reception problems with OTA TV, cable TV, satellite TV, etc.

>I'm a pretty good tech, and have fixed up and modified
>lots of stuff but now I'm going to have to do a lot of
>learning in the wild world of wire antennas and grounds.

My theory is that if it doesn't work on paper, it's not going to work
when you build it. There are plenty of "standard" antennas that
usually work the first time (if you follow instructions). However,
you seem to be interested in designing your own. Therefore, I suggest
you download the demo version of EZNEC, or the free 4NEC2, and proceed
to model your prospective antenna system. When the computah says that
you're close, then it's time to build it. An MFJ269 or similar
antenna analyzer is handy for verifying your calculations.

Hint: One of my ham friends moved into a CC&R (covenants, conditions
and restrictions) infested condo farm. No antennas of any kind. The
condo council had at least one member that was certain that property
values would decline if a ham was allowed to operate from the condo
farm. So, I leaned a 20ft aluminum extension ladder against the house
and ran a wire to the radio. It worke quite well with a tuner. The
ladder was left leaning against the condo for a bit less than a year

before the condo council discovered the ruse. There was a short debate. The council decided that since it had been in operation for a year without any complaints or detrimental effects, it could stay.

Luckily,in SoCal we don't contend with that very often -- Santa Ana winds in the canyons being the occasional exception. I feel for you.

Meanwhile, just hang up any old thing and agitate some 'trons. A 20m dipole at 15 feet (one end tied off to my chimney and the other end to a branch in my neighbor's macadamia nut tree) is all I have or apparently need. Yes, 1 KW into a SteppIR on a 50 foot tower is better, but at a cost of several thousand dollars per S-unit.

Really, it's all good. Maybe you heard my long-ago story about my 20m first-ever QSO with Hawaii. I got a 5-9 but the antenna was primitive: an existing 10m vertical dipole, with one end clipped to an extension ladder laying on the ground. True.

That is _so_ funny, I just got done mentioning my ladder experience!

The winds wasn't that bad. I live in a redwood, fir, oak, and madrone
forest, which blocks most of the wind. The problems are caused by
falling trees and limbs. I have a fair size ding in my car hood, and
had an oak tree land on my flat roof, destroying most of my antennas
and trashing in a skylight. Most of the shock was absorbed by my
neighbors roof.
<http://802.11junk.com/jeffl/pics/2011-12-03-Storm/>
So much for the idyllic life in the forest.

>KW into a SteppIR on a 50 foot tower is better, but at a cost of several
>thousand dollars per S-unit.

There's no way I can rotate a horizontal antenna without hitting a
tree or the hillside behind my house. A tower might help, if it were
200ft high, and the swaying trees won't hit the antenna. I'm stuck
with using wire antennas and verticals.

>Really, it's all good. Maybe you heard my long-ago story about my 20m
>first-ever QSO with Hawaii. I got a 5-9 but the antenna was primitive: an
>existing 10m vertical dipole, with one end clipped to an extension ladder
>laying on the ground. True.

Yep, RF is magic. I managed to make a QSO into a Heathkit Cantenna,
but that's about the limits of my non-traditional antenna experiments.
One of these days, I'm going to build an NEC2 model of an aluminum
ladder and see what can be done to use it on VHF or UHF.

So, I climbed up on my roof with a balun and some wire, intending to
make a dipole. Normally, this is a trivial exercise. However,
there's a problem. All the labels have peeled off my multitude of
coax cables. The labels were UV proof but apparently not water proof.
Almost all of my coax cables came off the same roll of RG6a/u and look
identical. This is going to be a problem.

I did manage to find all the parts to a Radio Shock discone antenna,
which is now simulating a wet noodle on top of a 10ft 3/4" PVC pipe.
That's because I can't find a single 10ft mast section that doesn't
have a fatal dent or bend.

The 12ft(?) long VHF/UHF Comet fiberglass antenna survived the tree fall, but will need to come down for some cleaning. The outside is covered with green slime. Experience has shown that when the outside is covered with green slime, so is the inside.

Maybe I should give up for the day, and just clean up the workbench.

After mucho years on the air in mucho locations I can say I've been
there, done that! This is however, my first real experience using a
very limited antenna and QRP.

I have an MFJ-259B -- couldn't live without it, and with all the
stuff I gave away this was the one thing that I just couldn't part with.

Good move! I've always maintained that if you give me any old
piece of metal almost anywhere, I'd find a way to load it and get
on the air! And I've done it time and time again. I did 26 years
in the navy and moved around a lot -- quick and simple antennas
were a must! I also helped a lot of chums who moved into
condos or rest homes get on the air using similar methods.

This case now though, is the first time I ever went into a place
that seemed impervious to signals. I've often operated from
indoors with no problem, and here, the first time I flashed up the
receiver, thought it had gone dead -- that's how bad it was. The
first thing I did was checked the protective diodes on the
antenna connector and as soon as I found them OK, opened
the window and strung a short wire outside -- then everything
was 5/9 plus!

As per another sailor many years ago said, 'I have not
yet begun to fight!'

For when you transmit into it by accident...
<http://802.11junk.com/jeffl/pics/2011-12-03-Storm/>
The MJF-259B is similar to the MFJ-269B, except that it lacks the
440MHz section. It's a very handy instrument, but is rather fragile
in that the detector diodes are connected directly to the RF
connector. One blast of too much RF, too much static electricity, or
even too much DC, and the diodes go poof.

Welcome to the joys of modern energy efficient construction. The
walls are full of aluminum foil backed insulation for both thermal and
acoustic insulation. The windows are coated with Low-E Titanium
Nitride IR reflective coatings (40 ohms per square), which also blocks
RF. The roofing material is carbon doped (instead of asbestos) which
absorbs RF. The foundation is concrete, which also absorbs RF.
Meanwhile, the proliferation of microprocessors, switching power
supplies, and BPL like devices, offers multiple sources of QRN. You
had it easy at previous locations.

>As per another sailor many years ago said, 'I have not
>yet begun to fight!'

Fighting is easy. It's negotiation that drives me nuts.

I kind of fell behind in my knowledge of modern constuction.
I lived in my house for 29-3/4 years and even though I did
a lot of renos, the infrastruction remained basically the same.
It is good though that they are getting smart on energy
efficient construction and other things -- hopefully we will
leave our kids and grandkids with a world pointed in the
right direction.

>
>>As per another sailor many years ago said, 'I have not
>>yet begun to fight!'
>
> Fighting is easy. It's negotiation that drives me nuts.

I'm on the air but not sure just how well I am getting
out, I don't want to measure it, I don't even care to
know since it is a whole different matter on QRP.
The proof will be in the pudding -- I may have to
wait for good band conditions, but the only
valid means of measurement will be the number
of QSO's and bands I can work.

From those lovely boxes of variable caps and
assorted inductors (some roller-inductors) and
a cheap 2nd hand 50ua meter I am going to build
up an artificial ground which is about as simple
a circuit as one can get -- the L&C in series and
make a sniffer out of the meter and a diode!. I
should have it all going in the next day or two --
as soon as I can get a round tooit. Yes. I admit --
I'm a master of procrastination

Well, on with the further adventures of
getting on the air to the point of satisfaction.
Is that a lot, I ask?

Thanks on the tips re the MFJ diodes. I'm aware
of them and can test and change them if need be.
So far, so good! I guess it wouldn't hurt to have
some on hand -- it's pretty inevitable that with
the experimentation etc, that I'll be doing some
or all will get blown before you can say poof!

Do you think that if I were to ask the management
here If I could have an aluminum ladder outside my
second floor window -- just to easy my mind about
the dangers of fire, they might agree?

Yep. It's happening, but very slowly and painfully. Ecology is
expensive in the short term, but worth the cost and effort.
Unfortunately, I've seen some abuse of power precipitated in the name
of the environment. Like all good things, environmental correctness
does attract a few flies.

>I'm on the air but not sure just how well I am getting

Oh rubbish. There are plenty of ways to test your setup that doesn't
involve calling CQ and getting a subjective signal report:
1. You can login to one of the remote radios or receivers on the
internet, tune to an empty frequency, and listen to yourself.
<http://beta.remotehams.com>
<http://www.dxzone.com/catalog/Internet_and_Radio/Online_Receivers/>
2. You can join one of the internet QRP clubs.
3. Weak Signal Propagation Reporter Network
<http://wsprnet.org>
4. Reverse Beacon Network:
<http://www.reversebeacon.net>
5. You can listen for beacons to check your receiver and antenna:
<http://www.ac6v.com/beacons.htm>
Our local radio club also has a remote HF station controllable over
the internet (using HRD) but it's only for club members.

>From those lovely boxes of variable caps and
>assorted inductors (some roller-inductors) and

All an artificial ground does is tune out the ground lead inductance
so that it's series resonant at the operating frequency. In effect,
you're building a counterpoise. You could user your MFJ-259B or a
grid dip meter to resonate the ground lead, and forget about the meter
and detector. However, if you must use a meter, I suggest a

thermocouple RF ammeter. Getting it to heat up the series resistor at
5 watts might be a challenge, but it can be done. Otherwise, it's a
current transfomer, ferrite core, diode detector, and 50ua meter.
<http://www.w1tag.com/RFA.htm>

>I'm a master of procrastination

I have a PHD in procrastination. Never do today what you get someone
else to do for you tomorrow.

>Is that a lot, I ask?

Yes, if you try to do it all at once.
No, if you take your time, grind the numbers, do a little planning,
and invite all your friends to help.

>Thanks on the tips re the MFJ diodes. I'm aware
>of them and can test and change them if need be.

I could only test the diodes after they were removed. The 50 ohm
resistors in the circuit prevented easy checking with an ohms guesser.

>So far, so good! I guess it wouldn't hurt to have
>some on hand -- it's pretty inevitable that with
>the experimentation etc, that I'll be doing some
>or all will get blown before you can say poof!

Yep. My experience is that certain users tend to blow up diodes no
matter what they do, while others don't have any problems. I'm sure
it's the user, not the analyzer. Possibly static build-up or
ungrounded antennas. Dunno.

I've been fairly lucky replacing all 4 diodes without needed to
calibrate the device. However, if you find the readings off after
replacement, see:
<http://www.w8ji.com/mfj-259b_calibration.htm>
The procedure took me 2 full days on an MFJ-269B. It went much
quicker after I read and followed the instructions.

>Do you think that if I were to ask the management
>here If I could have an aluminum ladder outside my
>second floor window -- just to easy my mind about
>the dangers of fire, they might agree?

No. Someone will probably try to steal the ladder. 20ft ladders are
not cheap. I ran two u-bolts through the ladder base, and permanently
attached the u-bolts to two foundation blocks with half a bag of
concrete mix in the hole. Various attempts were made to steal it, but
nobody got very far with 30 kg of buried excess weight attached. The
connecting antenna wire also acts as a capacitive alarm when the HF
radio is not being used. All this was only possible because each
condo had its own private back yard.

Another problem with a 2nd floor ladder is that you will be feeding the ladder from the top, rather than from the bottom. That will possibly work, but probably not as good as feeding the ladder from the bottom.

I won't care about subjective reports -- I'll be happy if
my few paltry watts that do escape the antenna get me
any kind of response. I am aware of the remote
receivers but I don't want to get so busy using other
things that I won't have time on the air making
plain good old fashioned QSOs. I will have a peek
at the internet QRP clubs as long as I don't lose
on air time going to meetings -- even on-air!

I considered that. I already have a group of radials
of various lengths on the floor -- I tied them together
with plastic ties for neatness, but with a ground tuner
I only need one which I plan to lay out along the edge
of the carpet -- that should make a neater job and if
I can tuck most of it under the baseboards it will not
frighten the houskeeper.

However, if you must use a meter, I suggest a

A simple diode detector may be enough, but if necessary
I'll have to line up ferrite core and get complicated.
>
>>I'm a master of procrastination

I was always good at procrastination however I did not consider
the part of having someone else do the work -- that's probably
why you have the PhD and I don't!!

That's the nice thing about being a retired senior -- I can take
all the time I want, and as you've seen in this thread, I'm
doing a lot of planning, and if necessary there I've got
lots of ham chums who will be anxious to lend a hand just
to get in here and see what I'm up to.
>
>>Thanks on the tips re the MFJ diodes. I'm aware

I never considered that -- oh well, it should only take a jiffy
to pop the diodes out although there is always Murphy to
take into account.

Now there's a very unhamlike suggestion -- wouldn't stopping
to read and follow the instructions severely slow down the
calibration procedure?

I've considered all the security precautions you took with the ladder.
At the moment I'm considering how to rotate it, and
wondering if I couldn't use a wooden ladder with lots
of wire stapled to it in a multiband Hentenna configuration!
I guess I may have to rethink it and take it one step at
a time! Now, I have to consider which rotor. Do you by

chance know offhand the wind load of a 20 ft Al ladder?
How about a folding ladder for the sake of extra length?
>
> Another problem with a 2nd floor ladder is that you will be feeding
> the ladder from the top, rather than from the bottom. That will
> possibly work, but probably not as good as feeding the ladder from the
> bottom.

I'll use double sideband so that it won't matter which end of
the ladder I feed it from!
>
Cheers, this is fun!

Umm... the diodes don't quite pop out in a jiffy. You must first tear
apart the instrument just to get to the diodes. They're tiny little
devils, best handled with stainless SMD tweezers.
<http://802.11junk.com/jeffl/crud/mfj-269b-diodes.jpg>
They're the 4 black things labeled "COB". If you order some from
Digikey or Mouser, be sure to get plenty of spares. I dropped two on
my workbench, where they promptly disappeared.

I consider reading instructions a sign of weakness, especially when
customers are watching. When they see me reading the docs, they
usually ask if I know what I'm doing, or if I had done this before. In
order to maintain my image, I try not to be seen reading the docs.

However, I do read the instructions..... after I'm done, and only to
see if I missed anything. On the MFJ-269B calibration, and after
starting over for the 3rd or 4th time, I decided that it might be
useful to just do it right, reading from beginning to end.

>chance know offhand the wind load of a 20 ft Al ladder?

No, but I could probably calculate the wind load if I had the
dimensions. Ice load will probably be the worst case. However, I
don't think a rotatable ladder would be a good or useful idea. The
ladder is mostly vertical, and rotation of a vertical doesn't do
anything useful. I suggest you leave it leaning against the building
and live with whatever that produces.

Incidentally, if there's anyone living directly below you, they may
object to having the ladder block their view. My friend's ladder
antenna was possible because his condo was a townhouse arrangement,
where he owned both the lower and upper windows.

>How about a folding ladder for the sake of extra length?

The 20ft ladder I used was a 2 section telescoping ladder. I had the not so bright idea of changing the length in order to tune the antenna to something near 1/4 wavelength. I also experimented with an insulating sleeve between the two sections in an attempt to make a vertical dipole. Both proved of dubious value as the best results were from using the full length ladder and an antenna tuner.

I'm not sure what a folding ladder will do except to add weight and attract unwanted attention. I just gave away two steel folding ladders. They weighed far too much but were admittedly quite useful.

>I'll use double sideband so that it won't matter which end of
>the ladder I feed it from!

Be sure to tilt your radio vertically to match the antenna polarization.

>Cheers, this is fun!

If it were easy, it would not be fun.

After I retired from the Navy I worked for Sony as a tech for 14
years and became pretty handy with SMD. When I retired from Sony
I kept my tools which included a headband magnifier and a few
different tweezers only one of which I consistently used. I do
recall losing one or two of the smaller SMD components but
I eventually learned to take precautions to avoid doing so..

With respect to taking things apart and then getting them
back together again I have to brag about my abilities. When
I had my first interview with Sony the asked me how much
of the work I considered electronic and how much was
mechanical. I estimated 90 percent mechanical (getting
the old part out and putting the new part in and then
the unit back together). I know now that it is more like
99.9%.

Oh well, I guess I'll just have to try and not blow
the diodes even though we both believe it will be
inevitable!

Scale back a little....
I put up a fan inverted -V cut for 80-40-30 a while back just to test.
I use a tuner, as long as the transmitter likes it, I like it.
I hardly ever use 80m, no particular reason, I just don't.
The ends droop to whatever was convenient. I did not bother to
consider anything permanent. Most of the ends are secured at the
perimeter of the yard via nylon braided line attached to military
surplus fiber glass mast sections leaning into convenient trees. I
only worried about keeping the ends high enough to avoid contact with
people, tractors and deer in the yard.

It seems to work well on all bands I have tried. Although I prefer my
manual MFJ tuner, the internal tuner in my TenTec Jupiter seems to do
OK. I am not a contester, a DX hound or a perfectionist but I do like
to spend a little time on the air.

I would make up a coax balun of about 8 turns of coax on a milk jug
with connectors appropriate to the roof connections. The Dollar Store
here sells black vinyl tape for about $1 for two rolls so wrap the
balun up well enough to not become a future problem. Pick any cable
handy on the roof, assuming that they all go to the shack. When you
get to the shack, use the cable that has signals on it.

I don't know which direction is favored on any band nor do I really
have any idea which elements are active under any given circumstance.

It will keep you on the air and give you time to decide where you want
to go from here with out undue pressure!

I worked for Sony/Superscope in Sunland-Tujunga California for a short
while in the mid 1960's. Too far to drive from where I was living and
going to skool.

>When I retired from Sony
>I kept my tools which included a headband magnifier and a few

Does your former boss know about this? Is there a reward for turning
you in? If you're going to pilfer the tools, at least take something
expensive.

I left one company with my junk parts box, my collection of component
samples, a DVM, and my favorite screwdriver. I probably could have
taken a load of test equipment, as nobody seemed to care. I figured
the dumpster would be full of junk after the layoff/purge. I was
right and collected quite a pile of goodies from the dumpster. I also
suspected that my project notes would be thrown away, so I grabbed
those. Many years later, the company raised one project from the dead
and called asking if I had any history on the project. Like a fool, I
just gave it to them, instead of demanding payment.

Like all products, my ancient products eventually hit the surplus
market. Like all good surplus equipment, there were no manuals to be
found. So, like a complete fool, I scanned the manuals and posted
them to my web pile. I now waste far too much time answering
questions and helping with repairs. Lesson learned: Products tend to
rise from the dead and will haunt you like zombies.

>I do
>recall losing one or two of the smaller SMD components but
>I eventually learned to take precautions to avoid doing so..

My standard precaution is to buy extra parts. The parts are cheap. My
time is not. I use metal egg trays for parts storage. However, I
also tend to tip those over or bury them in junk. My latest trick is
using semi-sticky window shelf paper to hold parts. That works great
after I remove the flies, bugs, and glue eating banana slugs.

>With respect to taking things apart and then getting them

Agreed. When I started in engineering, it was 99.9% engineering and 0.01% politics. 15 years or so later, it was 99.9% politics and 0.01% engineering. Productivity was about the same in both cases. Now that I'm officially in the repair biz, my guess is about 33% repair, 33% paper shuffling, and 33% customer ego support.

One nice thing about ham radio is that if I announce that I'm working on a project, and I procrastinate enough, then one of the local hams will eventually do it for me. See Tom Sawyer white washing a fence for details on how it works.

>Oh well, I guess I'll just have to try and not blow
>the diodes even though we both believe it will be
>inevitable!

Not really. As I previously ranted, only certain people seem to blow up the diodes. If you haven't blown any diodes by now, you're probably safe. Just don't loan it to any of your friends, especially on Field Day[1]. What seems to kill the analyzers is the act of plugging in and unplugging a PL-259 to the unit. The PL-259 is unique in that the center pin makes contact before the ground. This is what's commonly known as a lousy idea. If you've built up a static charge with your clothes and shoes, and are holding the shield, you'll discharge yourself through the center pin and directly into the diodes. That's my guess(tm) as to what's happening. I now make it a habit of touching the center pin to case ground, before plugging in. No clue if it helps, but it seems like a good idea. The N connector on the MFJ-269B should not have this problem, but they seem to blow up anyway, probably due to a different failure mechanism.

>Irv VE6BP

[1] Hint: Measure the DC voltage on the traditional Field Day balloon supported long wire antenna, especially if there's some wind. If the DVM doesn't explode, you're still not safe.

I actually asked permission. It is because I have always been
fair and honest that I am known as 'Fairly Honest Irv'.
I couldn't take any test equipment or the Fluke 77, but
I luckily picked one up for $25 at a flea market.

That's pretty common here in town. If an antenna is being
raised, even digging the hole for a tower, there is usually a
good turnout of the younger more able hams. Some say
that hams aren't like they used to be, but for the most part
I find them a good crowd.

I wouldn't even loan it to my mother, had she been a ham,
but I've carried it to a few hams but did the testing myself.
It cost more than most of my rigs!

Irv VE6BP

When I was still a pretty green ham, I heard a snapping noise
one night -- found it coming from the tuner! Wouldn't touch it
till it stopped! I eventually learned about wind static.

Reminiscent of an old story about how to establish
the height of a tall building with a barometer: Go to
the super and offer the barometer to him if he tells
you how tall the building is.

Also, drop it from the building's roof and time the fall.
d = 1/2 (g (t-squared)) Can also use a watermelon.

The "real" answer, involving atmospheric pressure
difference, is no fun at all.

"Sal"

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

If caught, I usually ask for forgiveness. It's easier than asking for
permission. I've gone by various names, none of which involve being
honest.

>I couldn't take any test equipment or the Fluke 77, but

>raised, even digging the hole for a tower, there is usually a
>good turnout of the younger more able hams. Some say
>that hams aren't like they used to be, but for the most part
>I find them a good crowd.

The local help is mixed. In general, a work crew can be organized,
but it's not like it was 20-30 years ago. The problem is that the
bulk of the ham population is aging and thus unable to do many of the
dumb and dangerous things that are considered normal for younger hams.
I gave up tower climbing at age=50 and steep roof climbing at age=60.
If I can't find a way to not trip over the coax cables and walk into
the guy wires on my roof, I may need to give up flat roofs.

When dealing with 100ft+ trees, I hire a professional tree climber. I
also have him prune the tree at the same time. I have two stainless
sailing blocks (pulleys) up in the trees for raising wire antennas.
Unfortunately, the rope used to raise the antenna rotted and broke. If
I can find an excuse, I'll hire a tree climber to replace the ropes.

>I wouldn't even loan it to my mother, had she been a ham,
>but I've carried it to a few hams but did the testing myself.
>It cost more than most of my rigs!

The MFJ-259B sells for $240 from various dealers. Your FT-817ND sells
new for about $600. Either you overpaid, or you're getting a sweet
deal on the radios.

If it's anywhere near a 1/2 wave dipole, a fan dipole shouldn't need a tuner. I've built two fan dipoles over the years. Since everything affects everything else, I spent far too much time adjusting the wire lengths. I eventually settled on a trapped dipole, which was easier and worked the first time. Either antenna would work for me except for the length. I don't have the room for a proper 80 meter dipole. For the immediate problem, I'll be happy if I can get on 20 meters (PSK31) and 10 meters (radio club net).

>It seems to work well on all bands I have tried. Although I prefer my

>OK.

Antenna tuners can be quite lossy. Have fun with this Java app:
<http://fermi.la.asu.edu/w9cf/tuner/tuner.html>

Do you have a field strength meter? Find a location in the pattern and as far away as practical. View the meter from your operating position using binoculars or a telescope. Try your fan dipole directly to the 50 ohm output of your transmitter. Hopefully, the VSWR will be less than what it takes to trip the VSWR protection circuitry. Now, install the antenna tuner and try again, keeping the RF power at the same level. If you have problems leveling the RF power, use an AC powermeter, such as a Kill-a-Watt, to measure the AC input power consumption. When I did the same test, the antenna tuner always had noticeably less TX signal strength.

>I am not a contester, a DX hound or a perfectionist but I do like
>to spend a little time on the air.

I spend more time inside the radios than in front of them.

>It will keep you on the air and give you time to decide where you want
>to go from here with out undue pressure!

The answer for me was supplied by outside influences. A mess of work arrived at my shop, so I'll be too busy to do antennas for a while.

FYI I spent an afternoon with EZNEC exploring fan dipoles.

What I found was the farther apart the wires, the less the interaction,
which is what one would expect from common sense.

From my limited runs it appears that somewhere around 20 degrees is about
where the minimum separation needs to be for practical length adjustments.

At angles less than that be prepared to spend a lot of time pruning.

It doesn't matter if the wires are separated vertically or horizontally
other than horizontal separatation means you need lots of support points.

If the bands are too close together, i.e. 20-17, 17-15, 12-10, you can
never get both bands to "work", i.e. a decent match.

That appears to be also true for trap antennas from some limited EZNEC
modeling.

Of course, there is always the alternative of throwing technology and
money at the problem and just put up whatever wire you can and put an
autotuner up.

The FT-817ND is my first store bought rig. Prior to my downfall
from good health, I always had either surplus which I'd converted,
or old rigs off the local Swap 'N Shops which needed repair. As
much as I say I'm going QRP, if I can pick up an old Kenwood
tube-job I think I'll give it a go! Unless I have a number of knobs
and switches to play with I sense a loss of control running the
new stuff.

A TS-820 or 830 would be great -- I had an
820 that really performed for me for a long time -- I gave it
away when I went in the hospital. I repaired a lot of Kenwoods
Swans and Yaesu's (not to mention other makes) for old-timers
and really enjoyed fixing them. I repaired a lot of the
newer solid-state rigs as well, but preferred the old
classics. I have a lead on the 820 I gave away, and may
end up getting it back. When I got it, it didn't have the
DC converter or the digital display but I managed to find
them on a cannibalized unit. It even had the
CW filter.. The only other thing I'd need would be
a keyer for a beautiful mint Bencher key I picked up
from an estate sale. The beauty of the Kenwoods is
that as long as 6146s and 12BY7s are available I know
I can keep them running.

<snip>

I have antenna challenged yard, with no available supports for horizontals.
So I've been experimenting with vertical radiators mounted on a 12 by 30
foot metal patio cover.

Initially, I used a CB whip, fed with RG-58 to a tuner in the shack, quite
successfully on 24 and 28 MHz. After a few more tests, (and more tests are
planned) I settled on a 14 foot radiator that works well on 20-10 meters.
It did a good job on all those bands during the recent DX contests, but
obviously won't bust a full fledged pileup without some operational cunning.

The antenna is fed with 25 feet of RG-8 to an RF ammeter in the shack and on
to a tuner. The ammeter is used to get the most current with various tuner
settings/configurations, but without changing anything from the ammeter to
the antenna.

So, a tuner in the shack feeding a single dipole might fit your band
coverage and real estate requirements. Play around a bit with EZNEC and try
a few things.

I've got 12 and 10 working fine together, seperated by about 8" giving a
decent match. It also works fine on 15 although no wires for 15, but a short
coax (20') to an ATU. It has a "pawsey stub" balun cut for about 17m (modeled
with NEC for best match with fan dipoles for all bands 20 -10, but I haven't
as yet got round to dipoles for 15 and below).

I was refering to the case where there is nothing to adjust the match and
getting something under 3:1 at the end of the feed line.

Given an ATU, you can usually match anything and there is no need for the
physical complexity of a fan dipole.

It was well within 1.5:1 within (part of) 10 and 12m bands.

>
> Given an ATU, you can usually match anything and there is no need for the

>
Very true The ATU is only used for 15,17 and 20, but my (larger) doublet
with tuned feeders is better for 20 and 17, and about the same for 15.

I'm currently debating whether to add additional dipoles to the fan or
replace it with a smaller doublet (about a half wave on 20), which would be
about half the size of the existing doublet.

I may end up trying both, I doubt if there will be much difference apart from
a slight change in directivity.

#
Given an ATU, you can usually match anything and there is no need for the
physical complexity of a fan dipole.

An open wire fed dipole would give pretty good performance. But, feeding
such an antenna with RG-8 and living with a high VSWR (maybe up to 10:1)
shouldn't be discarded.

A dipole of about 18 feet would cover 24 and 28 MHz with about 5:1
VSWR....not bad.

After spending several hours with EZNEC trying to get that combination under 5:1 with no success, I find that hard to believe unless something in the system is really lossy (like the feedline) and masking the SWR or the length of the feedline just happens to be at a length to help the match.

My transmitter gives up at about 5:1.

Your milage (and transmitter) may vary.

My transmitter gives up at about 5:1.

Your milage (and transmitter) may vary.

Yes. My Yaesu ATU gives up at 5:1, so I have been using a more robust
homebrew tuner.

A VSWR of up to say 10:1 (perhaps 15:1) shouldn't be a deal killer, if you
can match the coax and are willing to accept 2-3 dB of loss. This opens up
a lot of antenna possibilities that might be otherwise discarded.

Out in the YARD, on top of 30' of 1.25 inch semi rigid conduit I have a Solorcon A99 that looked like a fussy Popsicle stick that a friend of mine gave to me that I painted with some dollar general store paint - which tunes up with the internal antenna tuner in my Kenwood TS 590S - which is below 2:1 on 10 / 12 / 15 / and 17 even without the tuner - as long as you stay within the bands - 28.300 - 28.500 etc.... And will tune up beyond that - 26.950 / 29.690 MHz with the internal tuner...

Well, my trap inverted vee for 40-30-20-15-10 has a SWR of less than 2:1
where all my interests lie, and less than 1.5:1 on most bands.

Then there is the vertical that currently covers 160-10 at less than 1.3:1 on all frequencies for the days when I want to do something different.

It started out as about 33 feet of tubing for 40.

Wanting more, I built an enclosure containing a pair of relays and loading coils so it was less than 2:1 on the areas of interest on 160 and 80.

Wanting more, I mounted a SGC autotuner at the base so it is always 1.3:1 or less on all bands.

EZNEC analysis says the lobes are low, and actually have some low angle gain on 15 and 17, until I get to 12 and 10, where the lobes start pointing to the sky.

The next modification will likely be finding a 10 M trap at a swap meet and installing it at about 5/8 wavelengths to push the 10 M lobe down.

I can live without perfection on 12.

I had a 10-20 fan dipole laying on a roof for a while. Matched OK after a
bit of pruning but I abandoned it when I found both bands were better with
antennas that were clear of the roof.

I wonder something (and I suppose I'll have to try it, now) : Say I had a
20m horizontal dipole up at 30 feet, could I feed it through a coax that had
a Tee-connector located 22 feet up and simultaneously feed a 15m antenna
from that Tee-connector?

Just as they would be in parallel as a true fan dipole with a common feed
point, so also would they be in parallel -- just not sharing a common feed
point.

Normally I avoid Tee-connectors because they introduce the Evil Mismatch but
this time ...

I can see one problem already; some of the 15m energy that divides at the
Tee-connector would go up to the 20m antenna and be partially radiated and
partially reflected. Standing waves. The coax length would alter the
effect.

"Sal"

I've used those for many years.. Probably my #1 most used antenna.
I have them here at the house, and also up in the country at
the recreational living center.

>
> What I found was the farther apart the wires, the less the interaction,

Yep, and if at right angles, there is virtually no interaction at all.
I've had cases with dipoles at right angles where one leg broke off,
and the SWR for the unbroken intact dipole did not change.

yep, and it can get weird.. IE: the tuning appears to work backwards
from the norm.. It will almost always be one of the higher bands that
is effected. Rarely the lower band. And in many cases, you will end
up adding wire to the higher band dipole, to come up the band. A bit
peculiar, but I've seen it many times.

Not sure if I agree with that. I would think it *should* work if the
two dipoles are at right angles. And likely good nuff for gov work,
even if at a closer angle.
But it's not something I've really tested, as I generally don't worry
about the higher bands, and tend to load the lower band wires on the
higher bands. I rarely ever string dipoles for 17,15,12,or 10..
